At a recent meeting of the Académie de Médecine (February 14th) M. Regnauld presented a communication on the influence of impure chloroform in producing the gastric derangements which frequently accompany or follow surgical anæsthesia. M. Perrin, in 1878, considered that these symptoms were almost exclusively due to the impurity of the anæsthetic agent. As a simple means of testing chloroform, M. Regnauld recommends a solution of permanganate of potash, with the addition of a small quantity of hydrate of potash. A cubic centimeter of this solution is shaken up for about ten minutes, with five times the quantity of the suspected chloroform; if the mixture retains its beautiful purple violet color the chloroform is pure; if, on the contrary, it assumes a greenish tinge the anæsthetic agent is impure and unfit for use. To purify such chloroform, about one per cent. of pure concentrated sulphuric acid should be added to it, then after a few minutes the mixture may be decanted, shaken in a bottle with an excess of magnesia, and finally filtered. Chloroform treated in this manner does not take on a green tinge when shaken with the alkaline solution of permanganate of potash. Twenty samples of chloroform from different druggists were found more or less impure in all cases. M. Regnauld called attention to the destructive influence of solar radiation on chloroform kept in bottles.

In the discussion which followed, M. Gosselin stated that he would hesitate to admit that the impurity of the anæsthetic agent has any effect on the symptoms observed during chloroformization. Assuredly chloroform has caused death in perhaps 1 out of 5200 or 5300 cases in France, and in America in 1 out of 2500 or 3000 cases where chloroform was used to produce anæsthesia. Chloroform often induces cephalalgia, malaise, and protracted vomiting: but in the opinion of M. Gosselin these symptoms are due, not to the chloroform, but to some idiosyncrasy. To avoid these symptoms the chloroform should be administered methodically; the cornet or handkerchief being removed at short intervals, so that it may arrive in the lungs properly diluted.

M. Verneuil is of opinion that the odor of chloroform furnishes a very fair test of its purity. He considers, with M. Gosselin, that certain patients are peculiarly affected by this agent, and perhaps, among other causes, a great susceptibility of the pharynx to the local action of chloroform may induce spasm of the glottis, and the attacks of suffocation sometimes observed.

M. Perrin considers that the symptoms observed during chloroformization are not due to idiosyncrasy or the manner the anæsthetic agent is administered, as MM. Gosselin and Verneuil would have us believe. He is of opinion that chloroform recently made, pure, and which has not been exposed to the light, should alone be used for anæsthetic purposes.

Salicylate of Soda in Variola.

In the *Bulletin de Thérapeutique*, Dr. Baudon publishes the good results he has obtained in three cases of variola, by the use of the salicylic method. The first case was that of a man, 72 years old, who had been vaccinated in early youth. After three days, the face principally, and the whole body, showed signs of such an exuberant eruption as to warrant a most unfavorable prognosis. The case announced itself as one of confluent variola. The patient was in a state of great agitation, and it was a difficult matter to keep him in bed. Wine and brandy were prescribed, and taken without much trouble. So abundant was the eruption that the Doctor feared when suppuration set in the smell would be intolerable, and might prove infectious to the whole system. To guard against this, when that period drew near, the face and a great part of the body were anointed, thrice daily, with the following ointment:—

℞. Cold cream, ℥ iij
Salicylate of soda, ℥ j. M.

Besides this, the whole surface was dusted over with:—

℞. Talc, ℥ iij
Salicylic acid, ℥ iss. M.

The next day Dr. Baudon found the pustules had not increased in size, and the day after they began pitting; no pus was formed, nor was any smell developed. The parts not covered with ointment and powder underwent slight suppuration. Desiccation took place as usual, but the Doctor believed that the course adopted had averted serious impending results, among which the dangers to the attendants from the putrid smell were not the least. Delirium only lasted about three days, and ceased when the vesicles began pitting.

The daughter of the above patient was the next victim; she had been vaccinated but once. She was 23 years old, and her case was one of simple variola, although the eruption over the face was very abundant. Immediate applications of the ointment and powder soon brought about an abortment of the pustules.

The third case was that of a man, 35 years old, of weak constitution, who also had been vaccinated in infancy. The whole surface was covered with pustules. The ointment and powder were applied, and besides a tablespoonful of the following mixture was prescribed, to be taken every two hours:—

℞. Distilled water, f℥ iv
Salicylate of soda, ℥ j
Syrup, f℥ viiss. M.

Much to the Doctor's disappointment, the patient only took one spoonful of this mixture. Nevertheless, he soon recovered. Desiccation was rapid, and no pustules formed on the face.

In conclusion, we may say, that the foregoing method can do no harm, even if it has no other advantage than to do away with the repulsive exhalations, which are a source of danger to those around the patient.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Obstetric and Gynecological Literature, 1876–1880." By James R. Chadwick, M.D., Boston, Mass., comes to us as a reprint from the Boston *Medical and Surgical Journal*. In concluding this address, the author says, "To America I have no hesitation in according preëminence in this special field. Our countrymen meet the emergencies incident to child-bearing with a quickness of perception and readiness of action rarely seen in other countries."

——"Croupous Pneumonia; Is it a Zymotic Disease?" By D. W. Prentiss, A.M., M.D., Prof. Materia Medica and Therapeutics, National Medical College, Washington, D. C. An extract from the Transactions of the American Medical Association, 1881. His conclusions are as follows:—

1. Croupous pneumonia is an acute endemic disease, of zymotic origin.

2. The lung lesion is but a local manifestation of the constitutional disturbance, analogous to the ulceration of Peyer's glands in typhoid fever.

3. The specific cause remains undetermined.

4. The time of the year when the cause seems to be most active includes the months of January, February, and March.

5. The disease must run its course. Treatment should therefore be symptomatic and expectant.

——"A Case of Persistent Hyaloid Artery," by William S. Little, M.D., comes to us in the form of a reprint from the Transactions of the American Ophthalmological Society.

——Third annual report of the State Board of Health of Illinois, comes to us with the compliments of the Board. Along with this most complete and exhaustive model report, are blank forms, designed to collect information as to the number of persons vaccinated, and to further this practice, as well as a circular, in both English and German, setting forth the State laws on the subject of vaccination.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

JABORANDI.

As long as the "healing art" has been practiced we have been without a remedy which, when given internally, would induce as rapidly and as strong a diaphoresis as a drastic action of the bowels could be caused by medical means at our command. Certainly we could in many ways establish an increase in the function of the sweat follicles, but our materia medica did not enable us to induce always quickly a powerful action of the skin. In *jaborandi* we do not alone possess such a remedy, but by the hypodermic administration of its active principle, *pilocarpia*, we have the power to bring about, even during unconsciousness, an action of the skin that the best hot-air or steam bath would not be equally able to create. That a remedy so reliable and filling such a void in our materia medica should still be comparatively neglected by many members of our profession, as we know to be the case, we can only explain in this way: that nearly from the beginning of its introduction its use in cases of heart lesions was decried as too dangerous, while its main indication was often found in just such cases (as in uræmia, in cases of morbus Brightii, with dilated hypertrophy), and while its other qualities (absorbing power, diuretic, etc.) were rarely mentioned, so that a distrust was produced against a remedy, the usefulness of which cannot be over-estimated.

We will try to overcome the wrong impression, which has gained too much ground already, by mentioning once more the different preparations of this valuable article and the usual mode of their administration, and by illustrating in a few instances the great merit of this new addition to our not over-burdened resources.

The best and most reliable preparations of jaborandi for the practicing physician are, either the jaborandi leaves in the form of powder, or a good fluid extract, or the active principle, pilocarpia. The first are used either unaltered, as powder, which is perhaps the least effective mode of administration, or in form of an infusion, in both of which cases the single dose ranges from about thirty to sixty grains of the powder. We would prefer to either, however, a good fluid extract, of which adults take half a drachm in a small cup of hot or cold water, every half an hour, until four doses are taken. But far prompter in its action is the active principle, pilocarpia, of which the muriate or nitrate alone are employed, and in our country almost exclusively the first. Pilocarpia is preferred by many, as it can be used hypodermically, and its effect is then even more certain and undoubtedly more rapid, and besides, it is of special value in cases of unconsciousness, when the patient cannot swallow, points which have induced many to employ pilocarpia alone, and never jaborandi. Internally pilocarpia is generally given to adults, in doses of $\frac{1}{12}$ to $\frac{1}{6}$ of a grain, and more, and hypodermically in doses of $\frac{1}{16}$ to $\frac{1}{6}$ of a grain; in children doses have to be proportionally decreased.

If jaborandi is given in form of powder, infusion, or as fluid extract (℥ ss every half an hour), its peculiar effect usually sets in with the third or fourth dose; the internal administration of a sufficient dose of pilocarpia is mostly followed, within a half to one hour, by the expected result;

while the characteristic phenomena of pilocarpia, if given hypodermically, will almost invariably show themselves from within ten to twenty minutes, though it may be safer not to repeat the dose, nor to follow it by a larger one than the first, till at least an hour has passed. The effect of the remedy, in the vast majority of cases, consists in a more or less intense salivation and the most profuse sweating. But this is not all; a freer and decidedly increased flow of urine usually is also observed, and naturally, as the capillary vessels at the periphery are unloaded, to a great extent, of their fluid contents, and of salts the latter carry along, a general stimulation of absorption takes place, and we find not seldom, as one of the results of pilocarpia, a more or less total disappearance of morbid products, the gradual absorption of which we, perhaps for a long time before, had been uselessly trying to bring about by other so-called absorbing remedies. In a few exceptional cases the effects mentioned do not appear, and instead of them, only an excitement of the heart, a more or less violent flow of saliva, and a feeling of great exhaustion are noted. But there is almost no remedy for which some persons have not an idiosyncrasy, and besides, if, under proper precautions, as stimulation and the avoidance of such experiments in cases of grave heart lesions, etc., the dose of pilocarpia is pushed as far as safety may permit, and frequently enough repeated, the results first described will, even in these exceptional cases, mostly be obtained. For the purpose of producing absorption, or a slightly but continuously increased action of the salivary glands, the skin or the kidneys, pilocarpia is often administered for a longer time, also in very small doses regularly three times a day.

If the effect of pilocarpia is watched, and the correct dose given, there is no danger in its administration. Even in cases of affections of the heart this remedy may be employed; if, however, the condition of the organ ceases to be compensating for the lesion, and especially if great dilatation exists, it is safer to make use of stimulation at the same time, and to note carefully the result of the treatment.

The indications for the use of jaborandi or pilocarpia are, therefore, clear. Whenever we wish to produce not only a profuse perspiration, but the latter as rapidly as possible, the hypodermic administration of pilocarpia is to be preferred. Certainly, we do not wish to offend our readers by mentioning the cases in which patients might need a "thorough sweat" within a short time, but we may draw the attention to a few special instances in which pilocarpia acted remarkably well. So, in uræmic coma, it will often, by the increased perspiration, not only relieve the blood of its superabundant urea, but reestablish the urinary secretion, while the same remedy has saved, many a time, the life of children, when in cases of the acute exanthemata the eruption was inducing dangerous brain symptoms, either by being too long delayed, or by the exanthem, having fully appeared already, suddenly "going back." While in some cases of acute articular rheumatism, pilocarpia, if early enough employed, *i. e.*, while the joints are still stiff, but not as yet red and swollen, will often act like magic, and in other cases of the same disease rather do harm; its effect in acute anasarca (that form of dropsy which, occasionally, after a severe exposure to wet and cold, sets in suddenly with fever, and without the kidneys being necessarily implicated), will always be that of a specific; the œdema will disappear in less than an hour. Further, in cases of glaucoma, of pleuritic effusion, of phlegmasia alba dolens, this remedy has frequently stimulated absorption to such a degree that the cases proceeded favorably from the time of the administration of the pilocarpia, and the usual absorbents, which in the same cases before had uselessly been employed, seemed to act with renewed power. And here it is, especially, where in chronic cases the occasional administration of pilocarpia in doses sufficient to produce active perspiration is indicated: when we wish to bring about further absorption, and the action of our absorbents seems to flag; when the case has come to a disagreeable standstill. On account of the diaphoresis, pilocarpia requires great power of the heart for the time being, as a sufficient amount of blood has

to be forced to the surface to permit the congested capillaries to unload so much of the watery portion of the body, and we have to be, therefore, very careful with the use of such a remedy in grave affections of the heart, or when the organ is seriously weakened, and counteract any debilitating influence by the simultaneous employment of stimulants.

Our purpose is fulfilled, if we have encouraged a more frequent use of jaborandi, or of its active principle, muriate of pilocarpia, when active persiration, a freer diruesis, or an increased action of the salivary glands, or increased absorption are wanted, and if we have been able to convince some reader that the remedy is by no means a dangerous one if administered according to its effect. In conclusion, we will only add, that the reported favorable action of pilocarpia in diphtheria has not been sufficiently proven as yet, and that the remedy is utterly useless if employed to start on a bald head a rich growth of hair; while almost every form of alopecia, if caused by illness, seems to be favorably influenced if the individual so affected is put under a course of minute doses of muriate of pilocarpia.

HIGHER MEDICAL EDUCATION.

The results of the changes and advancements in the requirements for graduation in the Medical Department of the University of Pennsylvania have been most gratifying. When they were conceived, many old wiseacres gravely shook their heads and feared that the experiment would be a failure, and that it would be necessary to go back to the old regime. But the young and energetic men who inaugurated this new departure had not acted impulsively and hastily; on the contrary, they had for years carefully and cautiously considered the new arrangements in every detail, and minutely inspected the arguments for and against its ultimate success. Now, after five years only, the results that have been achieved amply testify to the wisdom of their course. For a year or two the attendance upon this old school slightly fell off. Young men who were ambitious to complete their studies in the shortest possible space of time, and with a minimum expenditure of effort, realizing that they could not do so at the University, transferred their studies to schools that offered a more lenient curriculum, and where the chances of securing the coveted degree were much greater. In time, however, and it required but a short time, the better class of students commenced to realize that this extended and graded course, while it required more labor and time, yet in the end would graduate them much more accomplished and competent physicians than were ground out under the old plan. Therefore they turned their student footsteps toward this institution of reformed medical teaching, and its classes once more began to assume their former magnitude.

The requirements for graduation, the various examinations, became more stringent, and the amount of practical work required from the students was very much increased. Now see the result. It was announced at the last commencement that 37 out of 159 candidates were unable to meet the graduation requirements; about twenty-three and one-half per cent. of the aspirants were rejected. This is formidable, and teaches, plainer than any words or announcement can do, that a young man must be very capable when he receives his diploma from the University of Pennsylvania. It was also stated that fifty-one received averages over ninety, with a maximum of one hundred; in other words, that (almost incredible as it may seem to old-time graduates) fifty-one per cent. of the total number of successful candidates received this enormous average.

In our time, under the old system, the averages were not made public, so that we cannot say much about them, but as an index of what they most probably used to be, we can speak authoritatively of the averages gained by forty recent graduates from various colleges when examined for the position of resident physician in the Philadelphia Hospital. Out of this number, *only four, or ten per cent.*, received averages over ninety. So that the evident qualifications of a young man to practice medicine, when he first

emerges from college, have been increased five-fold by this new departure.

The complimentary remarks made about this last class, by old and competent observers, quoted last week (in our report of the commencement) bears additional testimony, if any were needed beyond our statistics, that the Medical Department of the University of Pennsylvania has struck the keynote of true medical education.

When it becomes generally known what high averages, and consequently how thorough has been the education received by the alumni of this school, it will become necessary, as it certainly now is advisable, for all other medical colleges to follow its example.

America, or rather the United States, is a great country. We have great statesmen, equal to the leading political lights of any nation. We are an energetic, go-ahead people, destined, beyond doubt, to become, in the not very distant future, the *Rome* of modern times. As Oliver Wendell Holmes so beautifully expresses it, "the treasures of the British Museum and the Vatican" will find new homes in our hospitable and progressive land. And as a recent distinguished and lamented Frenchman once said to his confrères in the legislative halls of his country, "The pristine greatness of France has departed, never to return in its former glory. The French tongue is no longer the predominant language of the world; English has superseded it, and, unless I am very far wrong, it will not be many years before this language is principally taught from the banks of the *Hudson*." Realizing how great we are, and what a glorious future we have before us, in all the solid and material elements of national progress, as well as in the arts and sciences, it becomes eminently proper, and the time has come, when we should use every endeavor to raise the education of our young prospective doctors from that low level always found in what we might call *provincial* nations, and place it upon the level of the older and more advanced European countries.

All hail to the men who have inaugurated this new departure. When the time comes, as it surely will, and very soon, that the inhabitants of our southern and western neighboring nations; when the South Americans, New Zealanders, Chinese, Japanese, as well as the young doctors from Europe, will flock to the United States, as we now journey to Paris, Vienna, and Berlin, to finish the medical education but partially completed at home; then will the names of these pioneers in the region of unexplored "Higher Medical Education" be written and talked about, as now are the great medical savants of continental Europe. Their names will be as immortal as are those of Harvey, Hunter, or Vesalius. They will be looked upon as men whose efforts, when this country was yet young, were directed, with all the fire and force of their energetic natures, toward placing medical education on a true scientific basis. Keep on, gentlemen, turn not to the right nor to the left; go straight ahead in your grand and laudable path, and you will ultimately receive, as you now deserve, the hearty support and coöperation of every *sensible* man.

Notes and Comments.

Paralysis Treated by Extension.

Dr. C. R. Illingworth reports the following case in the *British Medical Journal*. A case of paralysis of five months' standing was brought to me. The patient was a young lad, aged 15, and the disease at first came upon him gradually, he being able to walk, although with difficulty for some weeks. There then occurred sudden and total loss of motion in the lower part of the body, and he was unable to either sit or stand up.

He had been systematically galvanized for three months, without any appreciable effect. Reflex motor power was impaired, but good. A peculiar forward protrusion of the chin, together with the above mentioned symptoms, led to a diagnosis of curvature in the cervical region, leading to paralysis of motion from pressure upon the anterior columns of the spinal cord, and it was decided to adopt gradual extension. The patient was laid upon a bed, the head of which was very much raised. The body, from the shoulders downward, was fixed to an upright pillar at the foot of the bed, by means of ropes attached to each side of a tightly fitting waistcoat, and extension of the head was then made, by means of a halter with chin-strap, pulling in

a direction running through the crown of the head. The extending power consisted of an elastic ring and metal chain, fixed to the halter. By putting the elastic on the stretch, and fixing the chain to an upright pillar at the head of the bed, continual gradual extension was secured, the chain being tightened a link or two as the elastic slackened. This apparatus was used during the day only, for two months, with very good results. In one month the patient began to move his toes, and every day afterwards the motor power returned to his lower limbs, and he became able to get up. A pulley was then fixed to the ceiling, and he was instructed to pull himself up by the rope, several times daily. In a few weeks he was able to walk with assistance, and four months after the commencement of treatment he could walk steadily and well, without help.

The Value of Pure Codeine.

In an article published in the *Journal de Thérapeutique*, Dr. Leblanc, says: The reason why authorities differ as to the merits of codeine, is probably due to the fact that it is frequently adulterated by admixture of *chlorhydrate of morphia*. Out of 100 samples of so called codeine syrup, recently examined, 23 were found not to contain a particle of this substance. As far as my observations go, I have found codeine to be a reliable soporific, valuable because of its mildness and the facility with which its effects are dispelled without leaving any unpleasant results. These effects are especially notable in cases of acute and subacute bronchitis, so much so, that I am inclined to believe this alkaloid possesses an elective sedative action on the mucous membranes of the bronchi and larynx. Under its influence the tickling sensations in the larynx, which induce coughing, are speedily calmed, and the patient falls into a quiet and refreshing sleep. Another advantage in favor of codeine is, that it is well tolerated by those persons who, owing to nervous temperaments, or from some unknown idiosyncrasy, are unable to take morphine.

There are a great many patients who, as it were, react against the effects of opium or morphia, either by experiencing nausea, or from a natural tendency to struggle against the hypnotic effects of morphia, as soon as they begin to be felt.

In such cases, *pure codeine* gives most excellent results; its effects are progressively soothing and culminate in a quiet sleep, unattended by either giddiness or those strange sensations, amounting often to delirium, which frequently accompany morphia.

From the foregoing observations, it would seem that codeine is a valuable remedy as a sedative in insomnia, colds, bronchitis, asthma, and whooping cough, provided it is perfectly pure.

Tonsillotomy by Ignipuncture.

The *British Medical Journal*, after commenting on the dangers of removing hypertrophied tonsils by all of the old methods, says: "It is now alleged that with the thermo-cautery this serious accident (hemorrhage) is no longer to be dreaded. M. Krishaber, who has tried it during two years, and has collected more than forty cases (*Annales des Maladies de l'Oreille et du Larynx*) has never had any accident after this treatment, and the results obtained have been lasting. It is likewise a novel application of a method which he has found perfectly successful for granulations of the larynx and pharynx. He proceeds as follows: The patient is placed—firmly, if a child—as if for laryngoscopic examination, in front of the operator, the mouth open, the tongue held back by a large spatula, the bottom of the throat well illuminated. M. Krishaber generally uses Paquelin's narrow-pointed thermo-cautery, heated to red heat. When it is only required to modify the nutrition of the gland, he gives preference to Trouvé's polyscopic galvano-cautery. The puncture of the gland, made as deeply as possible with the point of the instrument, should be repeated five or six times at each sitting. An interval of two or three days is left between the sittings, so as to allow the fall of the eschar, and to estimate the result. The operation is not at all painful, and pain, from burning, is rarely felt. Nothing need be administered after the operation, except, in some cases, a gargle of warm water, slightly carbolized.

Medical Treatment of Uterine Fibroids.

The medical treatment of fibrous tumors of the uterus is not absolutely fixed; subcutaneous injections of ergotine as a continuous treatment would be difficult to carry out, and electricity, which in the hands of M. Chéron has given good results, cannot be conveniently employed in private practice.

M. Chéron in the *Revue Méd-Chirurg. des Maladies des Femmes*, remarks that in many cases we will be obliged to have recourse to remedies which calm the pain and uneasiness felt in the abdomen, and to others having a resolvent action on the tissues of new formation.

For the first purpose he has found an ointment containing belladonna of great service, acting as a sedative and at the same time reducing the peripheric engorgement and causing a diminution in the volume of the tumor. His ointment is composed as follows:—

℞. Ext. digitalis, ℥j
Ext. belladonnæ, ℥ss
Ung. simplicis, ℥xss. M.

A portion of this ointment as large as a nut should be rubbed in over the abdomen night and morning.

The following solution has a decided resolvent action on tissues of new formation, and at the same time, as shown by Liegeois, a reconstituent action on the entire system:—

℞. Hydrarg. bichlorid., gr. ss
Aquæ destil., ℥viij. M.

A tablespoonful of this solution should be taken before each meal.

Resorcine and its Employment in Therapeutics.

MM. Dujardin-Beaumetz and Callias have made an extended study of this substance and its use, in the *Bull. Gén. de Thérapeutique.*

This substance was discovered by two Viennese chemists, Hlassiwetz and Barth, in 1860, among the products of fusion obtained by treating galbanum with potash; later on it was obtained from gum ammoniac and assafœtida.

Resorcine is very soluble in water, has a feeble odor, somewhat resembling that of carbolic and benzoic acid, and has the same properties as carbolic acid; a one per cent. solution acting as an anti-ferment, and a one and one-half per cent. solution as an antiputrid.

The authors are of opinion that this antiseptic, on account of its extreme solubility, its very feeble odor, its toxic effects being slight as compared with carbolic acid, it being also much less caustic, should be preferred to this latter in surgical practice.

Paget's Disease of the Nipple.

By Paget's Disease of the Nipple is understood a peculiar eczema-like affection of the nipple, which, though closely resembling eczema, differs from it in its well defined margin, in its intractability, and in that it invariably leads to cancer of the ducts, in middle-aged persons, if allowed to continue for some months. The relations of this disease were first pointed out by Paget, and hence the name. Munro relates several cases of the disease. In one of them, notwithstanding the nipple was removed before any symptoms of cancerous disease had appeared, the affection returned in the cicatrix, and was subsequently followed by cancer in the gland.

Ergot in Lead Palsy.

We read, in the *Lyon Médical*, that Dr. Stites recommends the following mixture in cases of hemiplegia and paralysis having their origin in chronic lead poisoning:—

℞. Potass. iodid., ℥ij
Ext. ergotæ fl., ℥j
Ext. nucis vomic. fl., ℥j
Tr. opii camph., ℥j
Syr. simplic., ℥iv. M.

A tablespoonful of this mixture may be taken night and morning.

A very great amelioration, if not complete cure, is obtained in about one month. The efficacy of ergot is explained by its well known action on the non-striated muscle fibres, and its long continued use does not seem to produce the results attributed to it (gangrene, etc.)

Cracked Nipples.

Le Paris Médical publishes a number of formulæ, which are recommended in this complaint:—

No. 1. ℞. Cosmoline, ℥xiiss
Liquid balsam Peru, ℥i½. M.

No. 2. ℞. Oxide of zinc, ℥i½
Cold cream or cosmoline, ℥x. M.

No. 3. ℞. Glycerole of starch, ℥viiss.
Oil of cade, ♏xlv. M.

No. 4. ℞. Cacao butter, ℥iiss
Oil sweet almonds, ℥ss
Extract of rhatany, ♏xv. M.

No. 5. ℞. Gutta percha, ℥j
Pure chloroform q. s. to dissolve.

By anointing the excoriations with this a slight film is formed, which will not become detached, even after sucking.

Knife Swallowed by an Infant.

The St. Louis *Courier of Medicine* reports the case of a boy, aged two years and five months, who, while playing with a two-bladed silver fruit knife, two and seven-eighths inches long, nine sixteenths of an inch wide, and one quarter of an inch thick, accidentally swallowed it, on December 27th, at 11.30 A.M. At the moment of its passing downward he became very red in the face, but beyond this experienced no discomfort whatever. On December 29th, at 9 A.M., forty-five hours and thirty minutes after it was swallowed, the knife was passed from the bowels, in a mass of consistent fecal matter.

Hoang-nan and Hydrophobia.

Paris Médicale reports that, at a sitting of the Société Médicale des Hôpitaux, January 27th, 1882, M. Gingeot read an account of a case of hydrophobia in man, treated with Hoang-nan, a medicinal substance used in the extreme Eastern countries as a remedy for a number of incurable diseases. Four pills were given, each containing grs. iss of the drug; but they were thrown up. M. Gingeot then had recourse to subcutaneous injections, dissolving the pills, and giving the value of two in each injection. The patient died, but he did not think this failure should condemn the process. In the first place, it should have been tried at an earlier stage of the disease, and then again, he believed that the right preparation to use as an injecting solution was the hydro-alcoholic, or an aceto-alcoholic extract of hoang-nan. M. Dujardin Beaumetz recalled the fact that during last year twenty-three deaths from rabies had been recorded in Paris. Different modes of treatment were used; but he gave his preference to the Russian method, which consists in the use of garlic, or sulphide of allyl, and thus far his patients had met with no accidents. He had made experiments with valdivin on mad dogs. This substance does not cure rabies, but it prevents the paroxysms. M. Sevestre observed that he had used pilocarpin, but without success.

Diphtheria.

Dr. Lolli, of Trieste, uses exclusively the following mixture in the treatment of diphtheria, and in sixty cases the mortality was less than two per cent., the malady having a duration of but eight or ten days, and being but rarely propagated to the mucous membrane of the respiratory organs:—

℞.	Ferri sesquichlorid.,	gr. xv–gr. xlv	
	Ac. carbolic pur.,	gr. xv–gr. xlv	
	Mel. rosæ,	℥ j	
	Aquæ calcis,	℥ xv.	M.

The throat is swabbed with this mixture every half hour, adults using it as a gargle, and it is, besides, to be taken in tablespoon doses, diluted every second hour. Of course tonics and very nourishing food form most important adjuncts to the treatment.

Arterial Elasticity.

The *Progrés Médical* reports that at a meeting of the Société de Biologie, on Feb. 11th, 1882, Mr. Arloing stated that he had measured the force of arterial elasticity, by counting the number of seconds during which this elasticity can, of itself, keep up the circulation of the blood. Having stopped the action of the heart by galvanizing the pneumogastric nerve, he observed that the blood continued its course during nine or ten seconds more; this he considers is an evidence that each arterial systole does more than simply to transmit the impulse it has just received.

Special Reports.

NO. IV.—ADULTERATIONS—(Continued).

SUGAR.

During the past year the attention of the Board of Health of New York city was called to the manufacture of a new kind of sugar by a secret process. It is made by mixing very carefully refined grape sugar with various grades of ordinary cane sugar. As the grape sugar is perfectly white, it, of course, gives a finer appearance to the dark sugars with which it is mixed, and as it costs only four or five cents a pound, considerable profit can be made. But the grape sugar used is made out of corn, sulphuric acid being used in the process. The new process sugar is not as sweet as cane sugar, but will be harmless, unless sulphuric acid or gypsum become mixed with it in its manufacture. This is a danger that may occur, and that renders the use of this sugar unadvisable. In connection with sugar we note that yellow candy is generally given its color by the use of the salts of lead, as much as seven grains of chromate of lead having been found in one pound of candy. The red is usually colored with cochineal, and is comparatively harmless.

COFFEE.

The Cincinnati *Medical News* says, "Ground coffee affords a field for adulteration, and for this purpose chicory, carrots, caramel and date seeds are the substances most commonly used. The beans have of late years been skillfully imitated, but as coffee is mostly purchased in the ground condition, the chief point for the consumer is to be able to form some idea as to the character of the latter article, and the following are a few simple and reliable tests: Take a little of the coffee and press it between the fingers, or give it a little squeeze in the paper in which it is bought; if genuine, it will *not* form a coherent mass, as coffee grains are hard and do not readily adhere to each other; but if the grains stick to each other and form a sort of '*cake*,' we may be pretty sure of adulteration in the shape of chicory, for the grains of chicory are softer and more open, and adhere without difficulty when squeezed. Again, if we place a few grains

in a saucer and moisten them with a little cold water, chicory will very quickly become soft, like bread crumbs, while coffee will take a long time to soften. A third test: take a wineglass or tumbler full of water, and gently drop a pinch of the ground coffee on the surface of the water, without stirring or agitating; genuine coffee will float for some time, while chicory or any other soft root will sink; and chicory or caramel will cause a yellowish or brownish color to diffuse rapidly through the water, while pure coffee will give no sensible tint under such circumstances for a considerable length of time. 'Coffee mixtures' or 'Coffee improvers,' should be avoided. They seldom consist of anything but chicory and caramel.

"French coffee, so widely used at present, is generally ground coffee, the beans of which have been roasted with a certain amount of sugar, which, coating over the bean, has retained more of the original aroma than in ordinary coffee, but this, of course, at the expense of the reduced percentage of coffee, due to the presence of the caramel."

New Remedies suggests another test for adulterated coffee. "It may not be generally known," it says, "that chicory, dandelion, and probably some other substances that are used for mixing with coffee, are readily deprived of color by a weak solution of chloride of lime (hypochlorite), and that this agent has very little action on the coffee. When this method is adopted, a portion of the coffee should be gently boiled a short time, in water with a little carbonate of soda, so as to remove extractive as much as possible; after subsidence, the liquor should be poured off and the residue washed with distilled water. When this has been sufficiently done, a weak solution of the hypochlorite of lime is to be added, and allowed to remain, with occasional stirring, until decoloration has taken place, which will probably be in two or three hours. The coffee will then form a dark stratum at the bottom of the glass, and the chicory a light and almost white stratum floating above it, and showing a clear and sharp line of separation." "The chicory, after this operation, is in the very best condition for microscopical examination, and it is not difficult to discriminate between chicory, dandelion or other substances. Although the lower stratum may be dark, and have all the appearance of coffee, other substances may be present, and should be sought for." Still another test has been offered by Mr. Albert Smith, in the *Pharmaceutical Journal*. "I have found the following method work very satisfactorily: First, carefully examine the coffee under the microscope; then take 150 grains of the coffee and boil it in two pints of water, then strain, and add diacetate of lead until a precipitate ceases to be formed; stir well and put aside to settle; if the coffee be pure, the water above the precipitate will be perfectly clear, but if chicory is present, the water will be more or less colored, according to the quantity present, which can be estimated by comparing the depth of color, the same as the Nessler test for ammonia." It has been stated that damaged raisins are roasted to make the French coffee.

It will be well for any one desiring pure coffee to resort to all these tests.

TEA.

C. M. Vorce, F.R.M.S., says, "In examining a sample of tea for adulteration, the first process is to sift it, or to otherwise separate the fine dust from the leaves. Having done this, put a quantity of the leaves to soak in warm water. On examining the dry dust with the microscope, if the tea is good, we shall find it to be almost entirely composed of fine fragments of the leaves, detached hairs, a few particles of Prussian blue, and such particles of sand, fibres, etc., as are always present in any substance that has been more or less exposed to dust. The poorer the sample of tea is, the greater will be the quantity of siftings, and the more dirt, dust, fibres and coloring matter are found; there usually is what appears to be simply dried and powdered blue clay. It is insoluble in water and apparently unaffected by acids." From this he infers that the cheap tea that shows this fine granular substance is sprinkled, while damp, with dry, powdered clay, which adheres to it as it dries, thus increasing its weight. It is also possible that the steeped leaves, which have served to furnish the extract of tea used to flavor other leaves, are thus treated with clay, so as to be sold again as tea at a low price. In the poorest sample of tea that he could find, such as retailed for twenty-five cents a pound, were discovered a large amount of stems of some bush, also pieces of the stalk of some grass, very like the common timothy grass, somewhat colored, and undoubtedly flavored by soaking in extract of tea. It contained many other impurities. Yet it had a good fragrance and taste, and when some of it was steeped and placed on the table, it was pronounced by those who tasted it (and who knew not of the adulterations) "*pretty good tea.*" Taking, now, the leaves which were put to soak, and which have unfolded and become soft, we proceed to minutely examine the structure of the leaves, so as to

know whether any leaves we may find in a sample purporting to be tea are tea leaves or not. The upper surface of the tea leaf is smooth, without hairs or stomata, and in its soft and swelled condition, when examined in water and glycerine with one-inch objective, shows the surface to be composed of angular cells, loosely arranged, some oval or circular, with considerable space between, with a tendency to fall into rows corresponding with the network of spiral vessels. An occasional clear space (an empty cell) looks like a hole extending into the leaf. The network of spiral vessels is very close and tortuous. The under surface bears many long, slender, simple, pointed hairs, without divisions. The cells are packed and the stomata very numerous; there are no open spaces to be seen. A section of the leaf shows that the cells on the upper side are attached by the end for two layers in depth; then come the T-shaped cells throughout the substance of the leaf, with one layer of cells lying flat on the under surface and gradually merging into the heterogeneous arrangement of the middle part. The cells of parenchyma forming the substance of the leaves are of various irregular shapes, but usually about twice as long as their width; many are triangular or T-shaped, and they are never circular or oval. The leaves of the very cheap tea were found to consist mostly of leaves having the shape of tea leaves, but somewhat smaller, and of a yellowish tinge. The cells were of very similar shape and arrangement to those of tea, but considerably smaller. The hairs were also of the same shape and size, but they were hollow quite to the tips, and so numerous, that in some places the leaf seemed entirely covered with them. The stomata were of the same size and shape as those of the tea leaf; and on the whole it seemed probable that these leaves were actually the leaves of some species of tea." Adulteration can be readily detected by any one who familiarizes himself with the structure of genuine tea leaves.

Correspondence.

A Case of Traumatic Tetanus—Recovery.

Ed. Med. and Surg. Reporter:—

On October 11th, 1881, J. G., a lad of eleven years, sustained a crush of the arm and forearm, by the flange of a moving car-wheel. The integument was split and loosened, and both it and the superficial layer of muscles devitalized. The arteries were intact, and no bones broken. The limb was poulticed and anodynes given as needed. Quinia and iron were ordered in tonic doses. The integument and portions of the superficial muscles sloughed around the entire circumference of the limb, from a point three inches above the elbow to near the wrist. The case progressed favorably till the thirteenth day, when stiffness of the jaw and general uneasiness began to appear. The weather at this time was damp and cool. Ten grains potassium bromide and three grains chloral were ordered every two hours. On the second day of the attack the jaw could be opened only one-fourth of an inch. On the third day the muscles of the back were so contracted as to draw the head back into the pillow, and any effort to change the boy's position caused the greatest pain. Breathing had become very difficult, from the tonic contraction of the chest-muscles. Urination also was difficult and painful. He complained of pain extending from the pit of the stomach to the back. Risus sardonicus was marked. Noises within or without the house gave rise to general spasm of the muscular system, accompanied by intense pain. The granulations of the wound became sluggish.

The patient's mind was clear and pulse normal. He was fed upon beef essence and milk, and one-eighth grain morphia was ordered at night. On the fifth day there was no material change in the lad's condition. A liniment of equal parts tincture aconite root, laudanum, ammonia water and olive oil, was ordered to be applied to the back of the neck and trunk, to diminish the cutaneous sensibility.

The treatment was continued, and on the eleventh day the symptoms began to ameliorate. The muscles of the jaw relaxed so that it could be opened half an inch. Contraction of the abdominal and dorsal muscles became less marked and the spasms occurred less frequently. From this period the boy steadily improved, but complained of stiffness and cramps in his legs, till the end of the fourth week.

Whether the bromide and chloral exerted any curative influence is a matter of doubt; still, recovery under their use, after an attack so severe, is worthy of record. James G. Buchanan, m.d.

Allegheny City, Pa.

Anacardium Poisoning.

Ed. Med. and Surg. Reporter:—

Having noticed in a medical journal a case of poisoning by anacardium occidentale, reported by Prof. F. Le Sieure Weir, and such cases being not well known to a large majority of practitioners, an account of a case that came under my notice may be of some benefit to many of your readers.

Mr. G. Z., aged 41, house sergeant at one of our Philadelphia police stations, had given him several cashew-nuts (anacardium occidentale) by a sailor, who brought them from Brazil, and was told that the kernel was edible and very sweet, but that the juice between the inner and outer shell was bitter. Mr. Z. did not profit by this warning, however, and commenced biting through the nuts, getting the juice on his lips and fingers. By the next morning his hands and face were largely œdematous and covered with erythematous patches, which in another day had developed into vesicles. The neck, body, scro-

tum and penis, which were greatly swollen, legs and feet, were attacked alternately, the treatment seeming to have the effect, as he said, of driving the disease out at the toes. Mr. Z. was confined to his bed during the second and third days, complaining of drowsiness and headache, and having a heavily coated tongue and high fever. The acute symptoms were over in eight days; desquamation continued for more than a week after.

The treatment, which was discontinued on the eighth day, consisted of a solution of sulphite of soda (℥ ij to Oj of water) applied to the affected parts every few hours, together with the following internal treatment:—

℞. Sulphate of magnesia, ℥ j
Tartar emetic, gr. $\frac{1}{16}$
Sulph. of morphia, gr. $\frac{1}{64}$
Water, ℥ ss. M.

given every two hours during the day.

H. B. Nightingale, M.D.

Philadelphia, Pa., Feb. 1882.

News and Miscellany.

Insanity.

From the report of Dr. Kirkbride, physician-in-chief of the Pennsylvania Hospital for the Insane, we note the following:—

Of the great number of patients lodged within the walls of the Pennsylvania Hospital for the Insane last year fifty-seven were cured, eleven much improved, forty four improved and twenty-six died. The records of this institution show that since 1841, of the 8480 patients received at the asylum 1577 were rendered insane through ill health; 828 from intemperance: 287, loss of property; 396, grief; 243, religious excitement; 87, overwork; 510, mental anxiety, and 13 from uncontrolled passion. In addition to these, fright caused mental aberration in 53 cases; metaphysical speculation, 1; engagement in a duel, 1; homesickness, 9; stock speculation, 2; mortified pride, 3; use of opium, 33; use of tobacco, 17; tight lacing, 1; sudden acquisition of wealth, 1. The ages of a majority of the patients when insanity first appeared was between twenty and thirty-five.

The improvements to the hospital during the year have been notable. The work of finishing up "The Mary Shields Ward" is now being prosecuted, and it will soon be in readiness. Thus far it has cost $25,866.52. The expenditures of the male department during the year were $79,214.14, and the receipts $81,692.25. The expenditures of the female department were $88,676.13, and the receipts $84,964.17.

The Clock Said His Time had Come.

About midnight, the other evening, the door bell of one of our physicians rang violently, and the doctor, putting his mouth to the speaking-tube, asked what was wanted. "I must see you right away," replied a voice. "But I am sick, and not able to attend to business," said the doctor. "No matter," said the voice. "I must see you, any way." The physician arose—it was bitter cold, and he was quite ill—donned his clothes, and proceeding to the front door, let in, along with a strong blast of zero air, a man and a woman. Neither looked very much out of health, but the man's eyes rolled rather wildly, and he appeared somewhat disturbed. "Well," said the physician, "what is the trouble?" "The trouble!" replied the man. "Trouble enough! You see, Doctor, we own an old-fashioned clock, that has stood on our mantel-piece for years. It has not been touched in all that time. Its works are dusty, and its case defaced by time. Would you believe it, Doctor? to night, after we had retired—that is, wife and I—all at once that old clock started up and struck the hour of twelve. Of course, Doctor, that meant my time had come, or a warning that I must soon die. What shall I do, Doctor?" And the man moaned and rocked to and fro, while the wife wept to see her husband so affected. The physician said he did not see how any prescriptions he could give would put off the fatal hour. But the man insisted, and finally the doctor gave him a prescription for bromide of potassium, with which man and wife departed, somewhat consoled.

American Butter in Ireland.

It is noted by the *Grocer* (*Medical Press and Circular*), that there has never been such a scarcity of butter in Ireland as there is at present, and what they have is almost uneatable. It is made up in "lumps," by the small cottagers, who have only one cow, and, therefore, have to keep the cream until it is semi-putrid, to churn it in a filthy cabin, full of turf smoke, and fetch it to market some days afterwards. This scarcity is being supplied by importation of American and Danish butter and butterine.

Guilds of Health.

Sir Henry Cole suggests, in the *Medical Times and Gazette*, that for the protection of health and prevention of fevers of all kinds, a guild of health, voluntary, self-supporting, and self managing, should be established throughout the kingdom, in every parish district at least, and that there should be a central station or office established in it, connected with some suitable shop, such as an ironmonger's turnery, etc., on the principle of post-offices. This suggestion might be acted upon in our own country with great benefit to our citizens.

Surgery Aids Music.

Dr. William A. Forbes recently performed the following unique operation: The connecting tendons from that of the third to those of the second and little fingers were divided subcutaneously in the hand of a pianist, by which he was afforded unusual freedom of movement of this finger, and was much aided thereby in his performances on the piano.

Prizes.

The International Committee of the Red Cross or Sick and Wounded Soldiers have offered prizes

of $400 for the best and $100 for the next best essays on the best means of improvising aids for wounded and sick. They are to be sent in before 1st of April, 1883. Further information may be obtained from the Secretary, *Rue de l'Athénée*, 8, *Geneva*. These prizes are open to competition by physicians in any country.

Sir Robert Christison's Successors.

Dr. Balfour, Emeritus Professor of Botany in the University of Edinburgh, will be proposed as successor to Sir Robert Christison, in the office of Assessor of the General Council in the University Court; and Dr. R. Peel Ritchie, F.R.C.P.E., will succeed him as consulting physician to the Royal Edinburgh Hospital for Sick Children.

Items.

—A Woman's Medical College has just been started in Baltimore. All the Professors are males.

—Gray's Anatomy has been translated into the Chinese language, and published in six volumes, at Foochow.

—A death from chloroform is reported as having recently occurred at Munich, in the case of a woman on whom a dental operation was being performed.

—Professor Panum, of Copenhagen, has been chosen to preside over the next International Medical Congress, and Dr. Carl Lange has been appointed general Secretary.

—"How are you and your wife coming on?" asked a Galveston man of a colored man. "She's run me off, boss." "What's the matter?" "I is to blame boss. I gave her a splendid white silk dress, and den she got so proud, she had no use for me. She 'lowed I was too dark to match de dress."

—Carlyle once rode sixty miles, to Edinburgh, to consult a doctor; "having," as he said, "reduced my perplexities to a single question: Is this disease curable by medicine? or is it chronic, incurable, except by regimen, if even so? This question I earnestly put, and got the response, 'It is all tobacco, sir; give up tobacco.' Gave it instantly and strictly up. Found, after long months, that I might as well have ridden sixty miles in the opposite direction, and poured my sorrows into the long, hairy ear of the first jackass I came upon, as into this medical man's, whose name I will not mention."

OBITUARY NOTICES.

DR. DAVID KING.

Dr. David King, an eminent physician of Rhode Island, died at his home in Newport, on the 7th of March. He belonged to one of the distinguished colonial families of New England, and was fifth in descent from Ensign Philip King, who resided in Raynham, Mass., in 1680. He was born in Newport, R. I., the 12th of May, 1812, and in his earlier school days attended the Academy at Kingston, R. I., and then Brown University, whence he was graduated with honor in the class of '31. He then began the study of medicine with his father, Dr. David King, Sr., but completed his course in 1834, in the Jefferson Medical College, Philadelphia. He then engaged in successful practice in his native city, and eventually became one of its wealthiest citizens. In 1850 he went abroad to visit, for professional information, the hospitals of Dublin, London and Paris. Returning the following year, he resumed practice, but in 1872 he again visited Europe, and spent two years in inspecting all the principal hospitals of the Continent. He contributed many professional papers to the Medical Society of his State, on several occasions receiving the principal prizes for competitive papers on special subjects.

He was successively Vice-President, President and Censor of the Rhode Island State Medical Society, and member of and delegate to the American Medical Association. Dr. King wrote and published several valuable papers on historical subjects. His literary and historical tastes led him to collect a rare and valuable library of many thousand volumes, much of the same character as the remarkable library of the late Mr. Brinley. During the war of the rebellion one of Dr. King's sons, serving with the Rhode Island contingent, was mortally wounded in the first battle of Bull Run. Dr. King was Assistant Treasurer and a member of the standing committee of the Rhode Island State Society of the Cincinnati. He leaves a wife and several sons and daughters.

DR. CLIFFORD MORROGH.

Dr. Clifford Morrogh, while riding through New Brunswick, N. J., about 5 o'clock on the afternoon of the 13th of March, fell back into the arms of Dr. Donahue, his student, and died just after reaching his home. He was 58 years old, and was a leading physician of the city. He was graduated from the University of New York in 1850.

QUERIES AND REPLIES.

W. S. A., Mo.—We have never heard such precautions as you refer to recommended by any one.

S. C. C., Ind.—Your first question is too vague; what do you mean by *cirrhosis* of the stomach? To your second question, Yes, under ordinary circumstances, although at times, the histological appearances approach each other very closely.

MARRIAGE.

CURTIN — ROBINSON. — At Hartford, Conn., March 21st, 1882, by the Rev. Jos. P. Taylor, of Camden, N. J., Roland G. Curtin, M.D., of Philadelphia, and Julia T. Robinson, daughter of Mr. Edwin Taylor, of Hartford.

DEATHS.

HARRIS.—In this city, on the 10th ultimo, Dr. Jas. S. Harris.

HASTINGS.—On February 27th, John McD. Hastings, M.D., son of Rev. J. M. Hastings, of Germantown, Pa., in the twenty-seventh year of his age.

TOMLINSON.—In Cincinnati, Ohio, Dr. I. H. Tomlinson, aged 59 years, of apoplexy, February 26th, 1882.

KING.—At Newport, R. I., March 7th, 1882, Dr. David King, aged 70 years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

ON BLOOD LETTING IN INFLAMMATORY DISEASES.

BY HIRAM CORSON, M.D.,

Of Conshohocken, Pa.

A physician in Illinois, in a personal letter, has criticised me pretty sharply for taking up so much space in showing the value of blood-letting in a single disease, and adds: "This senseless twaddle over cures made by medicines or remedies is getting worn threadbare; we need more teaching on the physiological action of medicines and less (fewer) specifics." Exactly what he means by this I do not know; but doubtless there is wisdom in it. I feel that I have taken up much of your space in the Reporter which, possibly, could have been better used; but this is so important a subject that men who have practiced a long time and proved the value of means of cure ought, in view of the fearful mortality which the present teaching of the medical colleges has produced, to speak out. I have this very day received a letter from a physician in Mifflin county, in which he says: When, eleven years ago, I graduated at the University of Pennsylvania, I received a letter from my father (then a practitioner of thirty years' standing) telling me to supply myself with a spring lancet and a hypodermic syringe. I well remember my thoughts about it. I could see some use in the hypodermic syringe, but none in the lancet; but being accustomed to obey, I bought it." He has used it, too, and prizes it above all price. Let us pause here to reflect on this: eleven years ago, and ever since, the teaching there has been *silence* in regard to this important mode of subduing inflammation, or *denunciation* of it. The teaching had been of a kind to make this young man and hundreds of others feel that it would be little better than murder; and these boys who were prepared to operate to remove an ovarian tumor or a stone from the bladder, were utterly ignorant of the art of opening a vein. How fearful has been the result of such teaching! Fifteen years of fearful mortality in a curable disease. Nor has it ended yet. Since the second of my papers was published, the young, ambitious, and useful Dr. Darrach, of Germantown, in the very bloom and vigor of manhood, was struck down; in three days after visiting a patient, when in his usual health, he was a corpse. So, too, one of the most prominent politicians of our county, an able and valuable man, passed away after a brief illness from pneumonia. I know enough of the treatment to know that the lancet had no agency in producing these sudden deaths, and that arterial sedatives, and stimulants, and food were urged most unremittingly. Sad as I am to record these deaths, and strong as is the desire within me to discourse more at length on the fatal mode of treatment in vogue, not only in Philadelphia, but all over the country, and which the eminent Professor Gross has not been able to bring into disrepute, although he has so well proved its danger, I shall pause here to give to your readers the views of Dr. John L. Atlee on the value of blood-letting in inflammatory diseases. No physician conversant with the history of medical and surgical science in this country needs to be told of whom I am now

speaking. Take him as surgeon and physician combined, and he is the equal of any living man in all our vast country. Sixty years of continuous practice at the bedside of the sick has given him an experience which only the ignorant and presumptious will disregard. Hear him!

"My Dear Dr. Corson—

"I have read with very great interest your communications in the Medical and Surgical Reporter upon the treatment of pneumonia and kindred inflammatory affections. They accord so fully with my experience, more especially in the earlier period of my professional career, that I feel it my duty to give you some of the results.

"And first let me say what has often been said before, but which daily experience strongly confirms, that 'the *fear* of debility has caused the death of thousands.' It may be true that within the period of the last half century our constitutions have undergone so great a change that what was formerly considered strictly antiphlogistic treatment in acute inflammatory diseases cannot, with safety, be adopted; that a 'sthenic' course is imperatively demanded; and that instead of direct depletion by venesection, local depletion, purgatives, cold applications and absolute diet, we must use those *medicines* which control the action of the heart; partially paralyze the nervous centres for a time; and to prevent debility, give diffusible stimulants, abundance of food, quinine, nux vomica, etc., etc.; and this at a time when the functions of digestion, assimilation and nutrition are measurably suspended. *Indirect* debility is mistaken for *direct*. We must relieve the already overladen horse by additional burdens!

"I must admit that since the advent of the cholera, in 1832, and more especially the influenza of 1847, there has been a change in the character of acute inflammatory diseases, which was not met with before; but I am as well satisfied that it is not so great as to proscribe, to so great an extent, those remedies upon the employment of which we thought the lives of our patients depended; nor do I think that the mortality has been diminished, but, on the contrary, increased, by the change.

"I cannot believe that the loss of from ten to twenty ounces of blood in the commencement of an acute disease—as, for instance, pneumonia, when the blood is driven into the delicate tissue of the lungs, already filled to repletion by the previous congestion; which loss will not only relieve the congestion, but lessen the reaction, by weakening the power of the heart—can produce as much real debility as the progress of the inflammation will do if we endeavor to control it by less decided and efficient remedies. It is disorganization and not real debility and exhaustion we have to fear; and it is organic lesion which is the cause of death in a vast majority of fatal cases. Post-mortem examinations prove this. In the early stage, with a full-corded pulse, there is no substitute for the lancet; and, in my own experience, I have found it, during the chill, or congestive stage which precedes the inflammatory reaction, to cut short the disease and rapidly restore the patient. In high febrile excitement it *unloads* the system, restores the suspended normal secretions, and awakens in it the dormant susceptibility to the effects of our medicines.

"Many years ago I was sent for to consult with a physician of large experience and of eminence in our county, in the case of a brother physician who had been ill ten or twelve days with an attack of bilious remittent fever, which was then very prevalent in his neighborhood. The attending physician wished to treat the patient as he had successfully done in other cases, by bark, as quinine, but he refused to take it and insisted upon the lancet. To decide between them I was called upon. I found the patient excessively pale and emaciated, with a small but corded pulse, complaining of excessive pain in the head, and saying that it felt as if it were surrounded with an iron hoop and somebody was riveting it on. He said he was certain the bark would only increase the difficulty. Upon consultation it was decided to support the patient in bed, in the sitting position, open a vein and bleed him until he fainted. This was done; as soon as he recovered, he exclaimed, 'Oh, Doctors, how good I feel!' The symptoms at once assumed a more favorable character, and after prescribing the necessary adjuvants, we left him. Two days afterward I visited him again, some sixteen miles from this city, and we found that for thirty-six hours he had remained free from pain, but that shortly before my arrival the severe pain in his head had returned. We sat him up in bed and bled him to fainting a second time. This was the end of it; he had no more fever, and had a rapid recovery. The *fear* of debility from venesection would have prevented its use, and the result might have been fatal.

"Some years after that I had a severe attack of bilious fever, from sleeping incautiously in a miasmatic locality. It was attended with intense pain in the head, and a feeling like that of my good friend, Dr. L., as if it was surrounded by an iron hoop and with every pulsation of the heart being riveted on. I sent for a physician and requested him to bleed me until I fainted. This required the loss of twenty ounces of blood, and was followed by prompt relief. Before the physician, who was engaged in conversation with my wife, had left the room, and almost as soon as reaction commenced, I felt a return of the same distressing pain. I requested him to tie up my arm and reopen the orifice. After losing ten or twelve ounces more I fainted again, and this was the end of my suffering. There was no return of fever, and the debility was not greater or more permanent than in my other fever cases where similar and apparently debilitating treatment had not been adopted. It is not unlikely that veratrum viride and quinine, etc., etc., would have restored me; but I would have suffered more and been less promptly relieved.

"I have bled in the cold stage of obstinate intermittents, with the effect of breaking up the paroxysms and preventing reaction, and with the relief of all the symptoms which usually accompany a regular attack of that disease. And could we but see our patients in the congestive stage of inflammatory diseases, and use the lancet before reaction commences, I believe that

many fatal cases might be prevented. How often do we not see epistaxis, and to a very great extent, prove critical and curative in the early, as well as the advanced stage of acute disease.

"Should any doubt arise as to the ability of the patient to bear the loss of blood, where the symptoms would indicate its propriety or necessity, we can do no harm by placing the patient in an upright position, opening a vein and watching the result. This I have repeatedly done, and I have never known mischief to come from it."

JNO. L. ATLEE.

Lancaster, Pa., April 5th, 1881.

Such is the testimony of Dr. John Atlee, and it is in exact accord with the testimony of his renowned and lamented brother, so emphatically declared in the meeting of the State Medical Society, at Easton, in 1875. After the publication of my second paper on pneumonia, the venerable Dr. Ezra Michener, one of the oldest and most eminent practitioners of Chester county, published an article in the *Country Practitioner*, of New Jersey, in which, after favorably referring to my article, he bore the most unqualified testimony to the value of blood-letting in all inflammatory affections; and while he admitted that there is an asthenic diathesis which debarred the present generation from using venesection and other measures of years ago, he has discovered that it is in the doctor's brain and not in the patient's body. I regret that space will not allow me to quote further from his valuable paper, which created a desire in Prof. Gross to corroborate his views, and impelled him to send his address on the "Lost Art" to the editor of the *Practitioner*, for publication. In a note to the editor he says: "From this paper you will see that Drs. Corson and Michener are not the only medical men who believe in the value of the abstraction of blood as a therapeutic measure. For, in the course of lectures which I annually deliver in Jefferson Medical College, I dwell with much force and emphasis upon the employment of the lancet in the early stages of inflammatory affections involving important structures before they have been overwhelmed by inflammatory exudations. *I wish to God that it was in my power to write this sentence, in letters of fire, upon the brain of every practicing physician and surgeon in the civilized world.* (Italics mine.)

"I have read Dr. Michener's article with much pleasure; it is a timely appeal to the common sense and judgment of practitioners, and I trust its warnings will receive attention."

With what appalling force these declarations of Doctors Atlee, Gross and Michener must fall on those who are losing patients with an illness of only a few days, and who stubbornly refuse to listen to the teaching of those earnest, able, and conscientious men who have handled and vanquished this disease countless times during the last half century. As I write memory brings before me the sudden deaths of Morton McMichael, Judge Cadwallader, Mr. Powers, and other prominent men, the pride of your city, suddenly carried away by a disease as certainly curable by proper means as almost any other, and which has no terrors for a physician who can use the lancet. But a few days ago an estimable lady, the wife of an eminent professor of Philadelphia, was swept away after a brief illness; and the papers have heralded the death of Rev. Dr. Vinton, from the same malady. I quote from the published statement of his illness.

"He arrived in Philadelphia on Wednesday evening, and on Thursday preached a sermon at the consecration services of the Church of the Holy Trinity. He was apparently in his usual robust health, but rose on Saturday morning feeling unwell. He was attended by an excellent physician, and subsequently, by a second. His disease proved to be pneumonia, and rapidly developed itself, with very alarming symptoms, and although accompanied with every possible aid of skillful medical and other care, terminated fatally." From this it appears he was well till Saturday morning, then rose "feeling unwell." A physician was called, and later, a second, and at 4 o'clock on Tuesday morning he died. His whole illness less than seventy-two hours.

But what of the treatment? Of it we have not a word. Can it be possible that the experience and advice, and earnest utterances of Dr. Gross, their revered colleague, who wished it was in his power to write his teachings, in favor of blood-letting in such cases, in letters of fire, on the brain of every practicing physician and surgeon in the civilized world, were disregarded? I tremble before the dread responsibility which, as physicians, we assume, and knowing how I have erred, will not arraign others, but entreat them to listen to the teachings of successful experience.

It does not satisfy me to be told that this or that skillful man was in attendance, and therefore I should rest assured that the best had been done for them. Let us hear the details of the illness and treatment of the many prominent citizens who have been snatched by Death from their families, while the physicians who so strongly condemn depletion by blood-letting, and boast so loudly of the potency of "antagonistic remedies," stood helpless and cowerin

before him. Histories of these cases would be more valuable to physicians in private practice, in city or country, than the "hospital reports" of cases of pneumonia in men and women whose debauched lives and dissolute habits, and whose long continued use of stimulants, have made them unfit subjects for such treatment as is imperative and so efficient in ordinary private practice. And here, I am bold to say, is the source of this fatal practice, which has spread with such fearful effect over our country. In all the great cities, the medical schools have medical control of the patients gathered in hospitals, and the practice thought to be efficient in these people, breathing the polluted air of their crowded homes, is daily proclaimed to the students, and by them carried to every section of our land.

Can it be, that in the presence of this great mortality, and the sorrow of homes made desolate, this stuffing, stimulating treatment, this exhibition of arterial sedatives with one hand and "heart tonics" with the other, shall go on, regardless of results?

In this effort to defend the treatment of acute inflammatory disease by blood-letting from the assaults made upon it by those who are ignorant of its efficiency, I have sometimes made aggressive war on the assailants, and have even wounded some of them; but if in doing so I have caused them to see the widespread and fatal results brought upon society by the reckless use of the weapons which they have wielded, or their ignorance of better, surer means of relief, I shall be paid for my labor, and society be relieved from its present fear of blood-letting.

A CASE OF ACUTE MILIARY TUBERCULOSIS.

BY H. W. RIHL, M.D.,
Of Philadelphia.

Mr. C., aged about 28 years, was tall and well proportioned; though vigorous-looking, he was languid in his manner, and was one of those to whom work seems always a burden rather than a pleasure. In the two or three years during which I was his family physician I had attended him several times. First, in June, 1879, I had prescribed bromide of potassium for paroxysms of what I supposed to be epilepsy. I had had no opportunity of seeing him in any of these, and was, therefore, compelled to make my diagnosis from the rather vague description given me of his symptoms on these occasions. After taking the bromide he was much improved, and my impression is that there was no recurrence. In July, 1880, he had intermittent fever, which lasted but a few days. In the same year, from September 4th to October 24th, he was under my care for a very severe pleuro-pneumonia, which involved the inferior half or two-thirds of the right lung, anteriorly and posteriorly. Some time after his convalescence, he resumed work at his trade—that of a printer. March 14th, 1881, he complained of weakness and cough. I was not at that time able to discover any disease in either lung.

On the 15th of last April I was summoned to attend him at his residence. He informed me that he had not been working for some time. He was confined to his bed, complaining of a very severe pain over the seventh rib, on the right side, about the point of union of the bone with its cartilage. There was little if any redness, and no swelling, but the pain was described as being exceedingly severe, persistent, and increased on the slightest pressure. It did not appear to be pleuritic, but directly under the skin. I questioned him very closely as to whether he had received a blow, or had fallen; but he was positive that he had not; that the pain had commenced a few hours before, and that he could not account for it. He was free from headache, and, with the exception of this pain, felt as well as he had for several months, though during that time he had not been strong enough to work. The pain was relieved by morphia, which he was obliged to take for three or four days, when a new train of symptoms made their appearance.

On my fourth visit, April 18th, my patient informed me that since my previous visit he experienced difficulty in moving his left arm. On examination I found partial paralysis of left arm and hand. This became worse, till, on the 22d, paralysis was complete—sensation as well as motion being much impaired. The left leg had also become paralyzed, but never to the same extent as the upper extremity. After my visit on the 18th (the day of the commencing paralysis), his wife called on me, and said that she could now give me the explanation of his trouble; that it had not occurred to her before, but that in a conversation with her husband that day they had recalled a circumstance which was a key to the whole difficulty. Three or four days before my first visit, she and her husband were in a crowded car; Mr. C. was standing, holding on to the strap. As they neared a point where the car turns westward he braced himself to encounter the shock of the curve; but instead of the car turning, it was drawn ahead, off of the track.

The concussion was so great that he was thrown some distance in the car, and became very sick. He returned home, and next day felt no further inconvenience, so that he had forgotten all about it till now. I told the family that where cars propelled by steam came into collision, troublesome nervous symptoms often resulted, but that I could not conceive that such could occur from a slight concussion in a street car, crowded as it was, unless there had been a previously diseased condition of the cerebral blood-vessels, when a slight cause might hasten the catastrophe which, sooner or later, would have happened without it. As the case became more grave I was inclined to consider this view as at least plausible.

The paralysis continued without much change till May 2d, when I commenced using Gaiffe's electro-magnetic battery. The improvement was rapid, and both arm and leg, in about eight days, regained much of their former power, so that patient was able to use his hand, and also to walk. For a few days the prospects of recovery became very bright; he was comfortable in every way; slept well and had a good appetite, and fair pulse. This apparent improvement lasted but a brief period. On the 15th I noticed, for the first time, that he had fever. I regret that I have not noted as often as I would now like, the condition of his pulse and temperature. From this time he grew rapidly worse. On the 17th I found him alone. On asking him how he felt, he made no reply to this, nor to several other questions. After a few moments he answered in monosyllables. As I was passing out of the door, he called me back and begged me not to be offended because he had not answered me at first, and gave as a reason, that he could not collect his thoughts. On my next visit, his wife informed me that he sometimes conversed without difficulty, and at others could not speak at all. He now seemed to have lost all power of sitting up or of using his limbs. On being placed on a chair he pitched forward and was utterly powerless to assist in getting in bed. On the 22d he had involuntary evacuations, which continued until the time of his death. On the 24th I noticed bronchial râles for the first time, on the right side. On the 26th Dr. Mills saw the case with me. I had stated to the family that there had been probably a cerebral hemorrhage. Dr. Mills took the same view, adding that meningitis of the convexity had probably followed a slight hemorrhage into or beneath the pia mater. Whether the hemorrhage had been caused by the jarring of the car, or not, was uncertain. May 27th, pulse 108; temperature 104° in the morning, 103° later in the day. May 29th, temperature 104°; urine contained a little albumen, a few granular tube casts, and granular epithelium; sp. gr. 1.020. On May 30th Dr. Mills again saw patient; his symptoms now bore a striking resemblance to typhoid fever; sordes about the teeth; low, muttering delirium; involuntary evacuations; slight bronchial râles; high temperature; frequent and feeble pulse; nothing but the rose colored spots and the previous history wanting, to make the likeness complete. On 31st temperature was 104½°, and on June 1st he died. June 2d a post-mortem was made by Drs. Mills and Eskridge, which revealed, as Dr. Mills will inform you more particularly, tuberculous deposits in brain, lungs, spleen and kidneys.

We are sometimes able to read articles which reflect much credit on our superior acuteness in diagnosis. You have probably already drawn the inference that such was not the object of the present paper, for though so many organs were diseased, and to such a great degree, I was at sea in regard to them all, perceiving no trouble in the lungs but the bronchial râles, nothing of the diesease of kidneys and spleen. All that I did know was that the brain was subjected to pressure, and the history given by the patient led me to consider the shaking up he had received as at least a plausible factor.

Even in the light of the post-mortem there are some features which still seem mysterious. One of these is the seemingly trivial nature of the disease at first, viz: the circumscribed local pain over the rib, not more than a couple of inches in extent, and in which no lesion was discoverable after death. Then how to account for the rapid disappearance of the paralysis after the use of electricity? Would this indicate that the paralysis was not owing directly to the pressure of the tubercles, but indirectly to the effusion of serum incident thereto, and the electricity caused the absorption of the latter?

The duration of the illness was six weeks. Roberts says the "usual duration is from two to eight weeks," that "no marked *physical signs* in connection with the lungs can be detected," and that it "may closely resemble typhoid fever." I will add, in answer to remarks made on this case, that dyspnœa was not marked till a few days before its close, and that there was not, till later in the case, a very frequent pulse, nor much cough.

NOTES OF THE POST-MORTEM EXAMINATION, AND REMARKS BY DR. CHAS. K. MILLS.

The skull was a little thinner than usual, especially in the parieto-temporal region. The dura

mater was adherent, at several points, to the skull-cap. On dissecting the dura of the convexity from the pia mater, they were also found adherent at several points, on both sides of the longitudinal fissure, in the postero-frontal and parietal regions. An irregular area of yellowish exudation or deposit, with more or less adhesion, was found between the membranes on the right side. This area was about five inches in length, along the median edge of the right hemisphere, in the postero-frontal and parietal regions, as already described, and converged to a point about one-and-a-half inches above the posterior third of the horizontal branch of the fissure of Sylvius, forming a somewhat irregular triangle, with its longest side along the median edge. The exudation was in patches in this district, and also extended downward in spots, on the median face of the brain, to the corpus callosum. A similar condition, but less marked, was found close to the median edge and on the median surface of the left hemisphere.

On stripping the pia mater of the right hemisphere, adhesions were found at points corresponding generally to the area of disease between the membranes. The region of the cortex involved in this adhesive inflammation was as follows: the upper half of the ascending frontal convolution, the posterior half-inch of the second frontal, posterior two inches of the first frontal, and one-and-a-half inches of the gyrus fornicatus.

On stripping the pia mater of the left hemisphere, it was found adherent above only along the median edge, but was irregularly adherent along the median surface down to the callosomarginal fissure.

No lesion was found at the base.

On examining the ventricles, ganglia and centrum ovale, the only lesion found was a small, hard, yellowish mass, in the posterior outer third of the right optic thalamus.

The right lung was adherent to the diaphragm and walls of the chest. The left lung was also adherent, but to a less extent. Both lungs were infiltrated with miliary tubercles.

The peritoneal covering of the spleen was studded with what appeared to be miliary tubercles.

The left kidney was small; and both in it and the right kidney miliary tubercles were found.

In the ileum, not far from the cæcum, was a small patch of ulceration.

After reading the notes of the post-mortem, Dr. Mills remarked that he had seen the case only a week before death, and had allowed himself to be led, somewhat by the history, to consider the condition of the brain only. His diagnosis had been meningeal hemorrhage, with inflammation of the meninges and exudation spreading from the original lesion. He had very positively indicated the *seat* of the brain lesion before death. The palsy was brachio-crural, *i. e.*, it involved the arm and leg, but not the face, of one side, which indicated the cortical motor region of the brain as the part diseased, in particular, the arm and leg centres. The partial recovery under treatment also pointed to the cortex as the situation of the lesion.

Dr. M. made a sketch of the brain upon the black-board, showing the principal convolutions of one side, and Ferrier's centres for the muscles of the leg, arm, speech, etc.; then outlining the chief deposit in the present case, he demonstrated how it confirmed the theory of localization in each particular. The anæsthesia might perhaps be accounted for by the small lesion found in the optic thalamus. He thought the present to be one of those rare cases of primary tubercle in the brain, with secondary involvement of the other organs, but with no demonstrable connection with the supposed injury.

Dr. Hall exhibited sections of the various organs under the microscope, showing the tubercles, and remarked of the specimens of the brain, that the disease deposit was limited to the surface, not following the vessels into the brain substance as much as usual in tubercular meningitis.

Dr. Eskridge thought it would be useful to recall the usual signs of miliary tubercle, as given in the text-books, in the light of such a case. We have absent the usual forerunning lung difficulty. The temperature vacillating and irregular, very high and very low, accompanied by profuse perspiration; these were all absent in this case. Pulse generally rapid or intermitting, not found. Respiration rapid, with bronchial râles; the râles alone being present in this case. Emaciation more rapid than the amount of fever indicates; which corresponded with that found in this case. Lastly, the ophthalmoscope, which seems to have been neglected in this instance, sometimes shows tubercles in the choroid, or an optic neuritis, when the disease is basilar.

Dr. Walker thought the diagnosis as regards the brain lesion a rather brilliant one, as the precise seat of the disease and its exact size was mapped out before death. Regarding the tuberculous nature of the deposit, and the involving of the other organs, he did not think a diagnosis possible under such conditions.

Dr. Beates said that the pathology of tubercle was sufficiently well known to settle the question of primary seat in any given case. A simple inspection ought to distinguish the recent, translucent, pearly tubercle from the older ones that had undergone caseous degeneration.

A CASE OF SUPPURATIVE SYNOVITIS OF THE KNEE JOINT.

Read before the J. Aitken Meigs Medical Association, of Philadelphia.

BY H. H. FREUND, M.D.

Willie C., aged four years, a healthy looking boy, without any ascertainable hereditary taint, on the 9th of August last, while playing with a footstool, slipped on the floor, a corroded sewing machine needle piercing the right knee joint, to a depth of three-quarters of an inch, the needle breaking off abruptly, at the cutaneous surface.

The needle, more accurately speaking, entered the joint at a point about one-third of an inch above and to the outer angle of the superior border of the patella.

At the time of occurrence of the injury no immediate symptoms were presented, the child merely remarking to its mother that it had stuck itself; nothing more was evinced by the child until the afternoon of the same day, when the mother noticed a painful expression upon the child's face, and questioning him, he referred the seat of pain to the affected knee. On examination, the joint was found to be swollen, particularly at the point of entrance of the needle, somewhat reddened and very painful to the touch; the mother detecting a sharp point of resistance, and thinking she encountered a foreign substance in the joint, carried the child to a prominent physician, who made an incision (the child being anæsthetized) and extracted the offending part of the needle.

A few days later constitutional symptoms developed; the child's sleep was not prolonged as formerly; sometimes crying out during the night; it became fretful and irritable, with loss of appetite, heavily coated tongue, and constipated bowels. With these symptoms there was also an evening increase in temperature, though of a remittent type. Coincident with the increase in severity of the constitutional symptoms, the local manifestations became more aggravated. The joint was immobile, painful on pressure, and all traces of its outline were effaced. The patella was freely movable and buoyed up from the articular surfaces of the joint by a fluid. There was no enlargement of the superficial cutaneous veins, nor was there at any time œdema of the extremity below the knee.

This condition was kept up for nearly three weeks, when a fluctuating point was discovered one-half inch below and to the right of the lower border of the patella. An incision was made, and three ounces of pus of a healthy nature escaped, more glutinous than ordinarily seen, evidently due to unchanged synovial fluid. After the pus cavity had been evacuated, an exploratory examination was made with a silver probe, which was freely movable over the articulating surfaces, and which conclusively proved that the joint was affected.

The synovial bursa beneath the patella must have shared in the destructive process, judging both from the point of ingress of the needle and the point of fluctuation of the pus cavity. The abscess continued to discharge small amounts of pus, until about the middle of October last, when it became much diminished in amount, and soon after the opening closed. With this closure the local inflammatory symptoms were much decreased in severity, the child regained its appetite, the secretory and excretory apparatus were again doing their normal work, and the child entered on convalescence. An interesting part of the history I must not forget to mention. After the incision had been made which gave vent to the pus, a mass of tissue protruded from the opening; this mass was as large as an ordinary sized adult little finger, and three inches in length; the surface was of a greenish-yellow color, having a beaded or fringed appearance; it was cut off by the mother, not producing any flow of blood. This mass, in all probability, was a part of a detached synovial fringe. Fungous granulations made their appearance around the orifice of the pus cavity, growing so rapidly that they had to be excised a number of times; the subsequent application of a pencil of nitrate of silver effectually prevented further growth. The seat of the pus formation must have been the synovial membrane of the joint; the cartilages of the articulating surfaces must have remained intact, from the fact that, at the present day, the little patient has perfect use of the limb.

The treatment throughout the case has been of the simplest, and can be dispatched in a few words. After the incision had been made, which allowed of easy extraction of the needle, the opening was immediately closed with adhesive strips and liq. acid. carbolic, applied by means of a flannel roller. The limb was put on a posterior angular splint; thus the joint was kept at rest. Later on the lotion was changed to lead

water and laudanum, applied by means of a large sponge, which passed nearly around the knee, thus accomplishing a twofold purpose—the application of an astringent and anodyne lotion, and the pressure afforded by means of the sponge (which was kept constantly wet), the sponge being confined by means of an ordinary roller. At the onset of the constitutional symptoms laxatives were given, with a quinine and iron solution, combined with milk, light broths, beef tea, and small amounts of sherry wine, frequently repeated. Small amounts of potas. iodid. were given, for its absorptive qualities. After the inflammatory symptoms had subsided, and the opening closed, a silicate of sodium dressing was applied, which aided much in the treatment.

To-day the child is in excellent health; it has regained its former vivacity, eats and sleeps well, and no inflammatory symptoms are visible. The patella has approximated its articular surfaces. He walks very well, and a casual observer would not recognize any defect in his gait.

PERMANENCE OF THE SCARLATINOUS VIRUS.

BY GEO. T. JENKINS, M.D.,
Of Keokuk, Iowa.

There has been a great deal said and written about the spontaneous origin of scarlatina, some claiming that unhygienic surroundings, sewer gas, filth, etc., may produce it, while the great majority of intelligent medical men believe the only source of origin is contagion. I have had physicians of large experience tell me they did not believe scarlet fever was contagious, but when I would present examples of its undoubted contagiousness, they would say, oh! well, they admitted it was epidemic, and this was as far as they would go.

It is nearly the universal testimony of recent authors and clinical investigators, that this disease is not only epidemic and contagious, but also that its contagious principle possesses very great permanency. There are several instances given by Dr. J. Lewis Smith, in his excellent work "On Diseases of Children," where the scarlatinous virus has remained in houses for months, notwithstanding careful disinfection was observed.

Sir Thomas Watson narrates an instance in which a strip of flannel remained contagious for at least a year, and Hildenbrand was infected by a cloak which, after exposure to the disease, had been put aside for eighteen months; hence we may assume that the morbific principle of scarlet fever is anything but volatile and unstable. I believe it is in consequence of the very great permanency of the scarlatinous virus that we have so many instances of the apparently spontaneous origin of this disease presented to our observation. We are unable to trace the source of contagion, either on account of our careless and superficial investigation, or its obscure manifestation, hence we conclude that it occurred spontaneously.

These thoughts were forcibly presented to my mind by a case that has recently come under my observation, which I deem of sufficient importance to be reported. I was called, on February 9th, 1882, to see Philip M., a child two years old, in consultation with Dr. Payne. The Doctor informed me that he had been in attendance upon the child for the past two days, and that his diagnosis was anginose scarlatina. The symptoms were characteristic and decided, and I unhesitatingly confirmed his diagnosis. The child died on the thirteenth day of the disease. The important point is the source of infection. It seemed obscure, and the parents insisted that the child had been nowhere to "catch the disease." It was the only child in the family; had not been away from home; there were no cases in that part of the city, and only three mild cases anywhere in the community, and in those contagion was easily established as a cause. We ascertained the fact that they had lost a child two years before with scarlatina, and that the child was just the same age of this little fellow. This led us to think probably some of the clothing might have been laid away without disinfecting, and saved till this child got to be about the same age and then put upon him. Upon inquiry we were told the child had worn none of his brother's clothing recently. When we called the next day, however, the mother exhibited a little woolen cap and said this was the only article of clothing that the child had worn recently that belonged to his brother. After further investigation we found that the child that died two years before had this cap on when he was taken sick, that it hung in the room during his illness, and that after the funeral it was put away in a closely covered tin box, without disinfecting. The box was air tight, and the cap had never been out of it until three days before our little patient was taken sick, when he wore it to a neighbor's and out on the street.

Both Dr. Payne and myself were fully satisfied, from the above circumstances, that the scarlatinous virus had been kept in that cap for two years. Why might it not, under the same careful process, be kept for ten years?

Hospital Reports.

PENNSYLVANIA HOSPITAL.

CLINIC OF JAMES H. HUTCHINSON, M.D.

Reported by Wm. H. Morrison, M.D.

Eczema of the Hands from Local Irritation; Bright's Disease, Complicated by Erysipelas of the Lower Extremities; Dropsy from Cardiac Disease.

Gentlemen:—Before bringing in any new cases, I shall show you a patient whom you saw last week, suffering from an eczematous condition of the hands, the result of having exposed them to an irritant. He was employed in cleaning out barrels which had contained fat. In doing this he used a strong solution of potash; this irritated the hands so much as to give rise to this marked attack of eczema. This does not really differ from the condition as it is sometimes seen in other occupations; for instance, it is not uncommon to have among grocers an eczematous condition of the hand, often called "grocers' itch." This is not due to the presence of an insect, but to irritant substances which they handle.

You will notice that the left hand has improved considerably under the treatment which has been employed. Last week it was swollen, the skin infiltrated, and there was a tendency to exude a thick, tenacious fluid. The condition of the left hand was at that time similar to that which we now see in the right. I first used starch poultices. In this condition the application of starch is often followed by great improvement. After the acute stage is passed we may use ointments, but to employ ointments in such a condition as we have in the right hand would do harm, for the ointment would soon become rancid, and act as an additional irritant.

In regard to constitutional treatment. It is, of course, questionable whether or not constitutional remedies are necessary where the disease is only a consequence of a local irritation, but thinking that, at all events, it would do no harm, I have put him on the use of Fowler's solution, five drops three times a day. It is well to order it to be taken immediately after meals, in fact, during the meal. Under these circumstances it is much less liable to produce nausea and vomiting.

The patient is doing very well, and in another week the right hand, will, I have no doubt, be in the condition of the left hand. Oxide of zinc ointment will be employed on the left hand, the starch poultices on the right, and the internal administration of arsenic continued.

BRIGHT'S DISEASE COMPLICATED BY ERYSIPELAS OF THE LOWER EXTREMITIES.

I shall now bring before you a case which I learn has been made the subject of a lecture by my colleague, a few weeks ago; but as his symptoms have somewhat changed since then, I thought that it would be instructive to bring him before you. He is fifteen years of age, but certainly does not look so old. He has been in the house since January 18th. The history is not very complete, but the main facts are these. Last November, without any apparent cause, he began to have pain in the back. This continued for some time, and was occasionally accompanied by nausea and vomiting. Soon after, swelling of the feet and legs was noticed, and later, swelling of the face. I have no doubt that a careful examination would have shown that the face was first swollen. Shortly after this the whole body became œdematous. The patient was not confined to bed before he came into the house. His mental condition is somewhat impaired, and this has made it difficult to get a correct history of the case. Upon admission, the whole body was œdematous, the tongue was moist and clean, the bowels regular, the urine had a specific gravity of 1.020, and contained about three-fourths albumen, by bulk; *i. e.*, when the urine was boiled and the albumen allowed to settle, it occupied about three-fourths of the former volume of the urine. This is, of course, a rough way of determining the quantity of albumen, but for practical purposes it will answer. Upon microscopical examination there were found hyaline, granular and epithelial casts, and later some fatty casts.

My colleague placed him on pilocarpin, one-eighth of a grain, twice daily. During the first twenty four hours after admission the patient passed twenty ounces of urine. On January 23d the bowels had been loose and he passed twenty-four ounces of urine. There was not much sweating, but the saliva was increased. On the 25th he passed thirty-eight ounces of urine. On the 30th, the day after I took charge of him, the quantity of urine had diminished, so that only ten ounces were passed; there was more œdema, nausea and vomiting; appetite poor; tongue coated and moist; bowels loose; legs more œdematous, and tender to the touch; hands also œdematous and some ascites. The pilocarpin was then stopped, and he was ordered infusion of digitalis, one drachm three or four times a day, and two drachms of the bitartrate of potassium, dissolved in a cupful of water, to be taken in the course of the day. The next day he passed more water, the œdema was somewhat relieved, and the patient was better. He was then ordered half an ounce of Basham's mixture three times a day.

The present condition of the patient, though still serious, is very much improved. You will notice that there is still œdema of the legs. This is, however, much less marked than it was ten days ago. You also notice on different parts of the legs an erythematous blush. This, also, was much more marked when I took charge of him. This redness has certain peculiarities. It does not shade off into the surrounding skin, but has a well marked border, and is tender to the touch. There is also a tendency to the formation of blebs. There is a large one on the left foot and several smaller ones on other parts of the leg. Again, we have a tendency for the redness, having appeared on one part, to leave this part and appear on another. This is not very common in the disease which I consider to be here present. In erysipelas, as it generally occurs, there is a tendency to spread, but it does not often leave one part and appear in another. There is one form of erysipelas (*érysipèle ambulante*) which is characterized by this tendency to skip; and there is another variety, *erysipelas erraticum*, or wandering erysipelas; but in this

case there has been, so to speak, actual jumps from one part to another.

We have then, in addition to the disease present when you last saw him, erysipelas of the lower extremities. Erysipelas occasionally occurs in the course of Bright's disease. You may recollect that when erysipelas attacks a person in a low condition of health, it is apt to affect the legs. Ordinarily the disease attacks the face, but in the great majority of such cases the patients are in fair general health; but in old persons and in persons debilitated by disease, erysipelas is prone to appear in the lower extremities. There is also, in œdematous limbs, a tendency to take on this inflammation. The fact that this complication may occur is an objection to certain methods of treatment which have been proposed to relieve œdema of the limbs. Acupuncture will often relieve the tension, but at the same time the little punctures which are made may be the starting points of erysipelatous inflammation. The œdema must have gone to a great extent, therefore, before I would recommend this plan of treatment. In this case the erysipelas appeared after the œdema had diminished. We find, then, a boy without a history of great exposure is attacked with pain in the back, nausea and vomiting, and shortly afterwards presents an œdematous condition of his lower extremities, followed, according to the history, by œdema of the face; but as I have said, if this patient had been living in a better class of society, the œdema of the eyelids would probably first have attracted attention. Œdema of the feet is often first noticed among people who pay little attention to their appearance, because the swelling renders the shoes tight. Although the history is silent on this point, it seems to me that this patient, most probably, either has been exposed to cold and wet, which in the great majority of cases is the exciting cause of the disease, or else, has had an attack of scarlet fever, so mild as not to attract attention. Bright's disease not unfrequently occurs after scarlet fever. I believe that in many cases where this disease follows scarlet fever the attack has been a mild one. I have now in my mind a case in point. A little girl had a very mild attack of scarlet fever; so mild that if I had not seen her at the very moment that I did, I should probably have failed to make the diagnosis. There were sore throat and fever, but the eruption was so slight, and continued for so short a time (for a few hours only) that I had a good deal of difficulty in persuading her mother that she had the disease. Two weeks afterward the patient began to pass blood; this continued for some weeks, and the Bright's disease, which was subsequently set up, continued for two or three years. I had begun to despair of the patient's recovery, when fortunately albumen disappeared permanently from the urine. Bright's disease may follow diseases other than scarlet fever. It may follow measles, erysipelas, occasionally typhus fever and diphtheria.

These symptoms, pain in the back, nausea and vomiting, and dropsy, all point to the kidney as the seat of the trouble; still these are not sufficient to make the diagnosis. I shall presently show you another case, in which there is as marked dropsy as here, but in which there is no disease of the kidney, or if there is any renal disease, it is secondary to the disease of the heart. I shall now test this patient's urine for albumen; first with nitric acid. It shows the presence of albumen very distinctly. You see a well-marked precipitate, which has the characteristics to which I have called attention on a previous occasion. It has a well-marked border above and below. It is as distinctly defined as if it had been cut with a knife; this is characteristic. We may have, from the addition of nitric acid to urine, a deposit of urates, but in such a case the precipitate is by no means so sharply defined as here, and it differs in appearance from this. I have before shown you how important it is to employ this test carefully and accurately. If I had simply poured the urine into the nitric acid, the precipitate would not have been so marked, and if I now agitate the liquid, the precipitate will be dissolved. By boiling we also have the precipitate. It is not as copious as it was two weeks ago. It does not now occupy more than one-sixth or one-eighth of the bulk of the liquid. Having obtained the precipitate by these two methods, we are pretty sure of the presence of albumen. Neither test is sufficient, but the two tests give definite and positive results. The urates may be thrown down by nitric acid, and the phosphates by heat, but the urates are redissolved by boiling, and the phosphates by nitric acid. It is also proper to take the specific gravity and the reaction, and to examine the urine microscopically. This has been done repeatedly in this case, and we have found well-marked casts. We have then, unquestionably, disease of the kidney.

It is necessary to examine the patient still further, to determine whether or not there is disease of any other organ. I have failed to find any disease of the liver, or of the heart. There has been heard at times a soft, systolic murmur over the base of the heart, but this is only a functional murmur, and due to anæmia. On auscultation, I hear œdematous râles over the lung. We have there the same condition that exists in the cellular tissue of other parts of the body. By very careful examination I can detect a slight amount of abdominal effusion. We have succeeded, then, not only in making the diagnosis of inflammation of the kidney, but also in eliminating any other disease as participating in the present condition of the patient. There is no other disease but Bright's disease present; there has not even been set up disease of the heart, which is so apt to occur in the course of Bright's disease.

This case may be said to be in the acute stage, just passing into the chronic. We have here the history lasting over a period of three months. We have, therefore, no longer an acute disease, but one becoming chronic. The condition of the kidneys is different from what it was in the early stages. They are probably less full of blood; they are paler, and probably present evidence of fatty degeneration. This is pretty certain, from the fact that fatty casts have been found in the urine. We have here a very grave condition. The patient, when I saw him for the first time, on Sunday week, was exceedingly ill. He had become much worse in

the few days during which my colleague was unable to see him. I found him with this erysipelatous condition of the lower extremities, suffering intensely with pain, exceedingly weak, œdematous and passing less water than natural. You remember that the treatment had consisted in the administration of pilocarpine. This appears at first to have produced a good effect, but after the remedy had been continued for a few days the good results passed away. When I took charge of the case it seemed to me not proper to continue this remedy. I am not quite sure that pilocarpine was indicated in this patient. In this disease there is a tendency to pass too little urine. Pilocarpine, by increasing perspiration, would have a tendency to still further diminish the amount of urine. It is therefore only in cases where the œdema is considerable, and where immediate relief is demanded, that pilocarpine is useful. The constant perspiration may have helped to bring on this erysipelas, which is certainly not a very common complication of Bright's disease in this house. I thought it better to put the patient at once upon diuretics. In Bright's disease the secreting substance of the kidney is diseased, and it may seem to you a questionable procedure to give the kidneys more to do; still, if you will consider the condition of the kidney, this objection will be found to be more theoretical than real. The tubes of the kidney are filled with debris which must be gotten rid of. This can only be done by increasing the flow of urine behind them, and thus washing them out.

I gave, therefore, cream of tartar, which is a good diuretic, in a large amount of water. Water is the best diuretic we have. It is rendered more diuretic by the addition of certain salts. I also gave him the infusion of digitalis, to act upon his kidneys, and also to stimulate his heart, which was feeble. Under this treatment he has improved considerably; the œdema has diminished in amount; he is able to lie down, which he could not do before, and the œdema of the lungs has diminished. I did not continue the cream of tartar, because it had a tendency to purge, and while purging is often an admirable way of getting rid of œdema, it is a weakening process. I then placed him on Basham's mixture, half an ounce three or four times a day. This is both a diuretic and also a tonic.

In regard to the treatment of the erysipelas. The iron in the Basham's mixture seems to have met some of the indications presented by this disease. The pain was so great that the limbs were wrapped up in laudanum and water. Lead water and laudanum would perhaps have been better, but this sometimes produces a deposit on the skin.

In reference to the prognosis. This is not very favorable. The evidences of disorganization of the kidney are very marked. The examination of the urine shows it; the general condition also shows it. He is, however, not beyond the possibility of improvement. We shall probably be able to effect a certain amount of improvement in his condition. We shall not be able, I think, to restore the kidneys to their former healthy condition. Such cases have been reported, but I have never had the good fortune to see them. I doubt very much if entire recovery ever takes place from this condition. Although all the other evidences of disease may pass away the albuminuria will still continue. Our views in regard to the presence of albumen in the urine have undergone considerable change since I was a medical student. When a resident in this hospital the presence of albumen in the urine was regarded as evidence of much more serious disease than now. We not only gave an unfavorable prognosis as regarded ultimate restoration, but as regarded life; but we now know that this is not the case. I know gentlemen in this city who are able to follow arduous occupations, who are active members of the bar, or active physicians, and who have had Bright's disease for a number of years and yet present little or no evidence of it: gentlemen whom, if you met them on the street, you would not suspect are the subjects of a serious disease. Recollect, however, that these men have a weak organ, and if they should be attacked by an acute disease of any kind, they would succumb more readily than a person who had not this disease. In other words, to use an illustration drawn from mechanics, "the strength of a chain is the strength of its weakest part," so that if a person with Bright's disease should contract pneumonia he would more readily succumb to it.

Let me here give you one caution: never allow a consultation to be called before you have examined the urine of your patient. This is an important point to recollect, unless you want to be mortified by its discovery afterwards, since very often the first question asked by the consultant is in regard to the presence of albuminuria.

DROPSY FROM CARDIAC DISEASE.

This is another case of dropsy, but the dropsy is here dependent upon a very different cause than in the last case. Dropsy is not a disease. Often, in the mortuary returns, you will see so many deaths from dropsy. This is only a confession of ignorance, since dropsy is only a symptom of disease. I show you, here, dropsy quite as marked, if not more marked than in the previous case, but in this man, examination of the urine at the present time does not show the slightest trace of albumen. The œdema of the lower extremities is very marked, with some tendency to the formation of blebs, but without any erysipelatous complication. The œdema extended considerably above the middle line of the body. The scrotum is distended. You will notice, however, that there is little or no œdema of the face. Œdema commencing in the face is generally attributable to kidney disease. Œdema beginning in the feet is just as often attributable to heart disease. In many cases we have disease of both organs combined. When we first examined this patient's urine, we found a specific gravity of 1.022, and a large amount of albumen (about one-third by bulk). This high specific gravity rather indicated that the albuminuria is dependent on disease of the heart. In disease of the kidney we have, generally, a low specific gravity, while in disease of the heart we often have a high specific gravity. I do not say that this is a rule without exception, but it will often help to distinguish the two diseases. No casts were found in this

man's urine. There were, then, no evidences of marked disease of the kidney.

Upon examining the heart we found the impulse diffused, rather outside of its usual position, and feeble. By percussion we have not been able to make out very definitely any enlargement of the organ. The reason of this is that the patient is the subject of emphysema of the lungs, which, consequently, cover the heart to a greater extent than normal. There is, however, no doubt in my mind, from the character of the impulse and of the sounds which are present, that we have enlargement of the heart with dilatation. As I listen over the apex, I hear very distinctly a systolic murmur. It is much obscured by the sonorous and sibilant râles which are heard in the chest and which are due to the œdema, but there is no question of there being a murmur. Yesterday, on getting him to hold his breath, I isolated the murmur very distinctly. I shall not ask him to do this to-day, as it brought on a severe fit of dyspnœa. The murmur is also heard at the left base of the heart, but not so distinctly. The same is true in regard to the right base. I do not think that this is a different murmur, but that it is the murmur transmitted from the apex, for it has the same characters and is much feebler. If there is any disease of the aortic orifice, it is secondary. There is no diastolic murmur; no evidence, therefore, of aortic regurgitation. We have here, then, a case of mitral regurgitation, mitral incompetency. A condition allowing the blood to regurgitate from the left ventricle into the left auricle, thus interfering very greatly with the circulation.

We have here a history of rheumatism. I shall rapidly read the history. "Family history is good. He had rheumatism in 1859. He enjoyed good health until one year ago, when, after exposure, he caught a severe cold, attended with much dyspnœa. This lasted for three weeks. Since then he has had attacks of shortness of breath. Six weeks ago he had an attack of dyspnœa. A few days afterward the feet began to swell. The dyspnœa has become more marked. The bowels are regular; the appetite poor. Lately he has been obliged to rise at night to pass water. No history of syphilis. He is anæmic and weak; pulse 110. The lungs are emphysematous and filled with râles. There is dilatation of the heart. The apex beat is diffused and most distinctly felt below the nipple. A systolic murmur is heard over the apex. The lower extremities are much swollen."

You will observe that the rheumatism occurred twenty-three years ago. It is very probable, from what we know, that the disease of the heart, which is now so prominent, occurred at that time. He then had, probably, some endocarditis, giving rise to the mitral incompetency. Why, then, has he not suffered before from this trouble? Because he has been in ordinarily good health. You notice that the symptoms from which he is now suffering began after an attack of cold. We have here an illustration of the fact I mentioned a few minutes ago, that a man with a weak organ is an unsound man. This man was not able to throw off this cold as readily as a man in perfect health, but instead, we have had an increase of the cardiac disease, as a result. You can readily understand that a bronchitis, which was probably the trouble which this patient had, would impede the action of the heart by interfering with the passage of the blood through the lungs. As long as the patient was in ordinary health he did not suffer from this disease of the heart but as soon as he became weak and debilitated, dilatation occurred and the symptoms that he now has began to appear.

We draw from this an important indication for treatment. We must try to restore him to his previous condition of health. The remedies required are not only those indicated by the disease of the heart, simply as such, but rather, those indicated by his general condition. Therefore, in addition to Basham's mixture and digitalis, indicated by the dropsy and the disease of the heart, I shall give him quinine, and later, if he can bear them, other remedies calculated to build him up. Cod-liver oil would be an admirable remedy, but I do not think he could bear it at the present time.

When the patient was admitted he was suffering greatly from the amount of the œdema, and in addition he had œdema of the lungs, causing great embarrassment of the respiration. The resident physician, very properly, placed him on purgative doses of elaterium. The object of this was, of course, to produce a copious discharge of water by the bowels. I have never seen it fail to give great relief where this condition is present. It is not a remedy to be continued for any length of time, because it produces great prostration. In the present case, in view of the urgency of the symptoms, the administration of this purgative was called for. At the present time the bowels are kept regularly moved, but drastic purgatives are no longer proper. I have placed him on Basham's mixture and the infusion of digitalis. Under this treatment he has improved considerably. I also gave him, in consequence of the condition of his lungs, the aromatic spirits of ammonia, as a stimulating expectorant.

In this case I made an unfavorable prognosis when the patient was first admitted. I hardly thought that he would live as long as he has. There has been, however, so much improvement that I hope he will become well enough to leave the house; but it is not likely that he will ever be able to do hard work again.

Tonic Pills.

The *Monthly Review of Medicine and Pharmacy* says the following tonic pills are much prescribed at the gynæcological clinic of the Hospital of the University of Pennsylvania:—

℞. Acid arseniosi,
Strychniæ sulph., āā gr. $\frac{1}{35}$
Ext. belladonnæ, gr. $\frac{1}{5}$
Cinchoniæ sulph., gr. iss
Pil. ferri carb., gr. iiss. M.
Et. ft. pil. No. j.

℞. Acid arseniosi, gr. $\frac{1}{35}$
Cinchoniæ sulph., gr. iss
Ferri et potass. tart., gr. ij M.
Et. ft. pil. No. j.

Editorial Department.

Periscope.

Puerperal Septicæmia.

Dr. J. S. Buck contributes the following case, illustrating the value of antiseptically washing out the uterus, to the *Medical Times and Gazette*:—

Mrs. M., married, aged twenty-eight, a multipara, aborted on Thursday, Oct. 27th, 1881. She was said to have been about three months pregnant, and was attended by a village midwife, who stated that "all the membranes came away whole," but that the patient lost a good deal of blood. I was sent for Nov. 1st. On my arrival I found her lying in bed, on her back, with her knees drawn up. Her countenance presented that peculiar sallow appearance usually seen in patients suffering from puerperal septicæmia. She appeared in a semi-conscious state. Temperature 104° F.; pulse 138, very small and thready. She had no lochial discharge whatever (this, I was informed, had ceased on Oct. 31st, the day previous to my seeing her). I ordered her one ounce of brandy every three hours, and gave her a mixture containing five grains of carbonate of ammonia, twenty minims of spirits of sulphuric ether, and one ounce of decoction of cinchona every four hours. On Nov. 2d patient seemed rather weaker, if anything. Temperature 104.4° F.; pulse 140, very small and thready. I continued the same treatment, only ordered the brandy every two hours, and repeated the chloral and bromide draught, as she had not slept. On the 3d, at 4 A.M., she had an attack of convulsions, which lasted about an hour, and in them she bit her tongue rather severely. At 2 P.M. she had another attack of convulsions, lasting about an hour and a half. On my visit she had a slight yellow discharge, which the nurse said smelt very badly. Temperature 104.4° F.; pulse 138, weak and thready. So I determined to wash out the uterus antiseptically. This I accomplished fairly easily, as I found the os uteri would admit the tips of two fingers nearly. I injected a quart of tepid, weak solution of permanganate of potash, which brought away a quantity of very offensive matter and shreds of membranes. I continued the brandy and ammonia treatment. On the 4th I was surprised to see the change in the patient. She had slept well without medicine. The pain in the abdomen which she complained of the day previous had ceased, her temperature had dropped to 101.6; her pulse was 120, much fuller and stronger, and she had had no more convulsions. I determined to give her another intra-uterine injection, which I did with some little difficulty, as I found the os somewhat smaller than on the day previous. I injected the same amount and of the same character, and brought away a few shreds of membrane, but it was not offensive at all. I ordered the brandy every four hours, and continued the ammonia and bark mixture. On the 5th she was much brighter and better. Temperature 101°; pulse 120. She slept well; no pain. I ordered the same treatment. On the 9th the patient was progressing well. Temperature 99 4°; pulse 96. She said she felt well and wanted to get up. I ordered her ten minims of dilute nitric acid and an ounce of the decoction of cinchona three times a day. On the 12th she was out of bed for about an hour. Temperature 99°; pulse 88; going on very well. 21st. Since the last note the patient had improved very much, and she is able to sit up all day. She takes her food well and sleeps well; has no discharge, and her temperature and pulse are normal. I have been giving her ten minims of the solution of dialysed iron three times a day, after food, and ordered her to continue taking it.

I think this case shows the good effects of antiseptically washing out the uterus in such cases. Dr. Playfair, in his "Science and Practice of Midwifery," speaks very highly of the practice, especially in those cases of "autogenetic origin," or self-infection as he terms them; and certainly, in my case, the effect was marvelous.

After Treatment of Lithotrity.

In a recent issue we furnished an abstract of a lecture by Sir Henry Thompson, on "Lithotrity at a Single Sitting." In continuance we can now furnish his remarks on the after treatment, which we glean from the *Lancet*: "When the patient has fully recovered from the ether, if suffering severely, say three or four hours after the operation, a condition which is quite uncommon, a hot hip bath, as hot as he can bear it for fifteen minutes, gives great relief. For the first three or four days the treatment will consist of recumbent position, external warmth, frequent hot hip baths, and small but frequent doses of solution of potash, to neutralize the acidity of the urine. If the urethra is over stretched or bruised, an india rubber catheter may be tied in for twenty-four hours or so; if the bladder had previously lost the power of emptying itself, such an inlying catheter for a day or two is better than frequent catheterism. It will sometimes occur, in the course of the most favorable cases, that on the fourth or fifth day a little excitement appears, the bladder becomes irritable, urine cloudy, and after twenty-four hours subacute cystitis is established, destined oftentimes to be troublesome for a week or two. To avoid this, great attention must be paid to the rest treatment noted above.

His proportion of deaths from the "*single sitting operation*" was only three per cent., while in four hundred cases, by the old method, reported to the Royal Medical and Chirurgical Society, the death rate was seven and one-half per cent. The mean age of the 101 men upon whom he operated was over sixty two years and a half. He thinks he is justified in concluding that the morbid condition of the bladder following lithotrity for uric acid and oxalate of lime calculi in previously healthy organs, occurs less frequently now than heretofore. In order to guard against

the danger, our first care should be to avoid in every case, where it is possible, the use of instruments, whether for crushing or evacuating, which over distend and irritate the urethra and neck of the bladder. Our rule must be not to employ larger instruments than the size of the stone demands. He cannot too earnestly warn the inexperienced operator against the needless risk he incurs when, in presence of a small or moderate-sized stone (and the majority met with belong to one of these two categories), he uses the heavy lithotrite and the large evacuating tubes which have of late been introduced into this country. In order to remove two or three hundred grains of calculous matter from the bladder—and many calculi weigh less than a hundred grains, while all ought to be found before they attain that weight—it is wholly unnecessary, I will even say it is unwarrantable, to introduce lithotrites and evacuators with the diameter of No. 18 or 20 English scale into the bladder. I am certain that the mere splitting, for it is not dilatation, of the urethra and neck of the bladder, which sometimes follows the introduction of such instruments, has sufficed to produce symptoms often distressingly painful, sometimes obstinate in duration, occasionally fatal. Surely it is more prudent to bestow two or three minutes more on the work, to ensure more complete crushing, so that the débris may be removed by a tube of 15 or 16 English diameter, than to crush coarsely and use an evacuator, which infallibly inflicts serious mischief in a certain proportion of cases.

I will briefly sum up our subject thus: Lithotrity completed at a single sitting is, in experienced hands, an operation unequaled in its safety for the patient.

It appears also to produce less subsequent persisting irritation of the bladder than the operation by several sittings.

No new form of instrument is required by this operation.

The value of the proceeding lies altogether in the removal of all the foreign matter from the bladder at once, so that nothing remains to excite inflammation, in an organ already irritated by the process. And the less irritating the operation has been, the more certain and more speedy will be the recovery.

It should be employed by beginners only for calculi of moderate size, when hard. If calculi are large, as well as hard, a young surgeon will probably proceed more safely by lithotomy. In friable phosphatic calculi size offers a much less serious difficulty. Lithotrity at a single sitting, for a hard calculus, upwards of an ounce in weight, and *à fortiori*, when double that weight, certainly demands an experienced operator.

Unusual Effect of the Sulphide of Calcium.

Dr. W. T. Alexander read a paper on this subject before the New York Dermatological Society (*Archives of Dermatology*), from which we extract the following: "Since the re-introduction to professional notice, by Ringer, Cane, and others, of the sulphide of calcium as a remedy for pustular acne, furuncles and other suppurative processes in the skin and glands, testimony as to its merits in these affections has been furnished by a large number of observers. But, in a very small number of cases that have recently come under my notice, the agent has seemed to exert an action so different from that usually ascribed to it in text books and communications to journals, that they seem sufficiently interesting to justify me in briefly reporting them." He then reports three cases. In the first, by mistake, the drug was taken in eight-grain doses three times daily, for several days. During this time the acne not only became worse, but several large, highly inflammatory, and exquisitely sensitive furuncles appeared on the wrists, forearms, and neck, attended with moderate febrile movement, gastric disturbances and diarrhœa. He then stopped taking the sulphide and the furuncles began at once to improve, becoming less painful, losing their inflammatory areolæ, and the previous purulent discharge from them ceasing. In the second case the drug was given in doses of one-tenth of a grain four times daily, for a small, indolent, painful, abortive furuncle on the back of the neck. In a few days, several large, intensely inflammatory, and very sensitive nodules appeared on the face, arms, and other parts of the body. As these symptoms were held to be simply manifestations of the original disease, the use of the drug was persisted in, the dose being increased. The furuncles became larger and more painful, until, finally, the patient having lost faith in the drug, it was abandoned, and she began to improve almost immediately, and was soon entirely well.

In the third case it was given in doses of one-fourth grain four times daily, with results precisely similar to the preceding two. That the pathological phenomena in these cases were not simply coincidences, but were due to the action of the sulphide of calcium, is rendered almost certain by the fact that recovery began in each of them immediately after the use of the agent was suspended. That they are not instances of drug aggravation is also rendered probable by the fact that in none of the cases was there any evidence of suppurative action in the skin before taking the medicine, and that this was a prominent element in all three of them after it had been taken for several days. Abundant testimony can be found showing the value of this agent in suppurative diseases, particularly occurring in the skin and its appendages, but that it is capable of *causing* such affections has been stated, as far as I know, by only one author. The most reasonable explanation of the pathological changes in these cases seems to be to attribute them to the influence of that indefinite and undiscoverable quality known as individual idiosyncracy or susceptibility to the perverse action of a particular agent, occasionally observed in practice.

The Sphygmograph.

The London *Lancet*, in an editorial plea for the more general use of the sphygmograph in private practice, thus well describes its merits. The height of the up-stroke made by the needle depends on conditions and methods of applying the instrument which deprive it of any significance, but its

direction, whether oblique or vertical, in relation to the rapidity of the movement of the paper, is of great suggestive moment. If the contraction of the left ventricle be free and the distribution of blood through the arterial system be unimpeded, the up-stroke will rise nearly at a right angle to the base line of the paper. If the impulse communicated to the blood-current by the heart be weak, or the vessels be rigid, so that they dilate slowly, the up-strokes will be oblique. Again, if the vessels be in a normal state and free, the down-stroke will commence with a sharp recoil at the instant of the subsidence or expiration of the force of the heart's action, as shown by the up-stroke. The juncture of the up-stroke and the down-stroke will therefore be acute. The rapidity of the fall shows the state of the vessels, as regards their rigidity. The contraction of the vessel, which is a reaction upon the dilatation effected by the impulse communicated to the blood-current by the heart, produces a second rise, generally half-way along the down stroke. This rise, which marks the arterial element of the pulse phenomenon, bears a relation to the up-stroke which is not affected by the mode of applying the instrument, and it is, therefore, of great value. The chief points of practical value which the sphygmograph shows may therefore be enumerated as follows. The force and freedom of the ventricular impulse in relation to the state of the arteries ; the condition of the coats of the arteries in relation to the question of their rigidity or elasticity ; the condition of the muscular coats of the arteries as indicated by the power of contraction possessed by the vessels and their excitability, as evidenced by the quickness and extent of their contraction as a reaction on the impression produced by the heart's action. This contraction is a true reflex acting through and in the vaso-motor system. The question of blood-tension is also, as it were, raised, and partially, though not fully, discussed by the behavior of the needle of the sphygmograph. Enough, therefore, may clearly be learned by the use of this instrument to render it of high practical value even to the busy practitioner, and it is of interest to the progress of our art that it should be generally employed. The discredit into which it has fallen has resulted from the not unnatural enthusiasm of its introducers, who made too much of it, and exaggerated the importance, while they misconstrued the nature, of the lessons it has to teach, and the aid which, when rightly used, it can render.

The Nerve Element in Whooping Cough.

The *Lancet* says: Of late years the profession has bestowed very little, if any, serious scientific attention on some of the commonest of common maladies. Whooping-cough is conspicuously among the neglected ills to which, notwithstanding the forgetfulness of the multitude of earnest clinical investigators, flesh is still heir. Many years ago the nerve-element in this troublesome and too often evil-working, if not in itself dangerous affection, engaged much consideration, and treatment was specially directed to its relief. It would be well if the investigation of this feature of the etiology of the affection could be resumed. The fact that pertussis belongs to the class of maladies which are communicable and "catching" does not take it out of the range of probability that the specific action of a morbific poison on the nerve centres may be the efficient cause of the disease. Although the occurrence of the affection happening rarely more than once in the life of any individual may seem to point more directly to the fertilizing of latent germs in the organism than to any special excitation of the nerve centres, we do not, as yet, know enough of the *modus operandi* of morbific influences—"germs," or poisons as we may call them—in the blood and the tissues to define the part which the nerve centres play in the production of morbid phenomena. In any case, such relief is frequently obtained, even in the earliest stages of whooping-cough, from mild periodic counter-irritation over the whole length of the spinal column by a mustard poultice, which merely reddens the skin without vesication, that it would be well worth while to study this method closely from the therapeutic as well as the clinical standpoint. It certainly does good ; but how? In cases where the mustard poultice, applied for six or eight minutes—not longer—over the whole length of the spine immediately before putting the child to bed, every night, for a week, or, in seriously spasmodic cases, a fortnight, does not procure a permanent amelioration of the cough, the effect of this remedy is enhanced by sponging the spine with iced water quickly, each successive morning. In cases where the paroxysms of cough seem to be repeated and to continue from sheer exhaustion of the nerve centres, coffee, administered as a drink, will often stimulate the energy of the centres so as to put an end to the malady. These are practical points which require theoretical explanation.

Delirium Tremens.

At a recent meeting of the Cambridge (Eng.) Medical Society (*Lancet*), Dr. Latham introduced the subject of the treatment of delirium tremens. He thought the subject offered scope for considerable difference of opinion, and was a suitable one for general discussion. He referred, first, to sleeplessness as a prominent symptom, and said that if sleep were obtained, recovery generally ensued quickly. Was the induction of sleep, then, a *sine qua non* in treatment? If sleep did not ensue, subarachnoid effusion and coma were likely to follow in some cases, while the majority might recover ; but Dr. Latham thought the disease ought to be treated actively, and that dangerous remedies might be used with advantage to patients. He divided cases of delirium tremens into three clases: (1) Patients in moderate health who had used stimulants in excess ; (2) those in robust health who had indulged after excitement or distress, chiefly young men ; and, (3) those broken down in health, and with damaged organs. The first class he thought could be treated with opium, without risk, provided the urine was free from albumen ; and he had been surprised to find albumen in the urine in a large proportion of cases without any other

indications of kidney disease, and the albumen disappearing as the patient recovered. If albuminuria existed, the use of opium or morphia could only be pernicious. The first thing to do was to give soup, beef-tea, and alcohol in nearly the accustomed doses for twenty-four hours, and then opium; having previously given, if necessary, a dose of calomel. He advised the hypodermic injection of morphia, first in half-grain doses, and then in doses of one-quarter-grain every half hour till sleep was procured or the patient was distinctly under its influence, as shown by the condition of the pupil. He believed diminution in quantity of stimulants taken by the patient to be an early symptom, and not a cause of the disease. In the second class he advised, not opium, but henbane. He had given bromide of potassium in forty-grain doses every four hours, and found the tincture of henbane in doses of one drachm every four hours succeeded better. He also thought that Merck's preparation of hyoscyamine would be useful, but had not yet given it a trial. In the third class he thought opium should be given with great caution, and that the free administration of stimulants was important, even as large doses as those customary with the patient. He mentioned a case in which a gentleman, in his eager desire for insensibility, had taken 240 grains of chloral and the same quantity of bromide of potassium at a dose, and survived after very free action of the skin, bowels, and kidneys. He deprecated the use of large doses of digitalis, as suggested by Dr. Jones, of Jersey. Mr. T. Hyde Hills, speaking from his experience as a jail surgeon, thought leaving off stimulants was a cause of the disease, and that many prisoners became delirious after admission, owing to this deprivation. He advised giving the usual amount of alcohol to which the prisoner had been accustomed, and thought chloral of benefit. Mr. Hodson thought that the combination of chloral and capsicum was useful. Dr. Smith alluded to the usefulness of cold sponging of the body, as a means of inducing sleep. Dr. Latham, in reply, stated that he recognized the capsicum in confirmed cases; it was much esteemed in India. In young men he approved of Dr. Graves' plan of giving antimony and opium every two hours.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the eleventh annual report of the Philadelphia Dispensary for Skin Diseases.

—— "A Case of Prolapse of the Laryngeal Sac," by J. Solis Cohen, M D., comes to us in the form of a reprint from the *Archives of Laryngology*, Vol. III, No. 1, January, 1882.

——"An Experimental and Clinical Inquiry into the Etiology and Distinctive Peculiarities of Traumatic Fever," by B. A. Watson, M.D. This comes to us in the form of an extract from the Transactions of the American Medical Association.

——"Preliminary Observations on the Pathology of Sea Sickness," by J. A. Irwin, M.A. Cantab., M.D. Dub., comes to us in the form of a reprint from the *Lancet*. In this pamphlet the author (who is preparing a work on sea-sickness) lays before the profession the substance of some novel views which he entertains upon the pathology.

——"Abortion and its Lessons," by O. E. Herrick, M.D., a reprint from the *Michigan Medical News*. In this article, the author takes the ground that when a good cause exists, abortion is justifiable. He considers injections used immediately after connection the surest means of preventing conception.

They should be used with a vaginal syringe, with a large speculum pipe as large as an ordinary glass tubular speculum, with the rubber bulb attached directly to the end of the speculum pipe and no rubber tubing intervening.

Plain water will not answer, but if carbolic acid is added to it, it will often prevent conception. After injecting the liquid, the rubber bulb of the syringe should be allowed to expand, when all the contents of the vagina will be drawn into it.

BOOK NOTICES.

An Index of Physiology. By L. Ashley Faught, D.D.S., late lecturer on Physiology in the Philadelphia Dental College, etc., etc. pp. 120. Press of Wm. H. Hoskins, 913 Arch street, Philadelphia. 1881. Price $1.00.

The author claims that this is the smallest book on physiology ever published, and we imagine he is right. In his title he modestly claims for his production the merits only of an index, and as such we can commend it. Those who can afford to buy it will probably not learn much that they do not already know, but a glance through its pages may assist them in their further study of the more elaborate volumes on the subject.

Home and Climatic Treatment of Pulmonary Consumption, on the Basis of Modern Doctrines. By J. Hilgard Tyndale, M.D., Member N. Y. County Medical Society, etc., etc. pp. 174. New York: Bermingham & Co. 1882. Price 50c.

This volume is a resume of the therapeutics of all progressively destructive processes of the respiratory organs which do not occur successively and rapidly in the train of acute inflammations of the lung. It is a good book, well worth the small price asked for it.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SYPHILITIC CACHEXIA.

It frequently happens, more particularly in systems previously broken down by intemperance or neglect, that syphilis fails to run its usual course. Instead of (as the books tell us it does) eventually getting well of itself in time, after running an active course for some weeks or months, maybe a year or more, some of its manifestations will settle down into a slow, chronic, indolent condition, as it were, and will seem as though they intended to remain forever. Thus *lupus* may have been the chief outward manifestation of the disease. After some months these sores may degenerate into indolent ulcers, over the surface of which may form a hard, elevated, scaly scab, underneath which there is a constant secretion of pus, which, oozing out from some little portion of the scab, will repulsively soil the underclothing.

Or rheumatism in all the joints may remain, to remind the man of his folly, after all the outward manifestations of the disease have disappeared. There are numberless souvenirs of this disease that may exist in the chronic condition referred to, when, from collateral considerations, we have good reason to believe that the active specific poison has lost its virulence, or has been removed from the body. In such conditions, anti-syphilitic treatment, the various forms of mercury, the iodides, tonics innumerable, have all been tried, and yet the obstinate symptoms continue, as uninfluenced by treatment as though you had prescribed *aqua pura.*

If now you will use the compound decoction of sarsaparilla, made according to the Pharmacopœia, in a majority of cases you will derive astonishing results. This treatment of syphilitic cachexia, more particularly of syphilitic rheumatism, has been recently brought into notice again by a writer in an English journal, and it promises great things in this obstinate condition. We do not mean to treat syphilis with it, but do recommend it in this after condition. If chronic ulcerations exist, it will be necessary, in addition, to touch them occasionally with a point of lunar caustic.

This decoction contains sarsaparilla, bark of sassafras, guaiac wood, liquorice root and mezereon. To commence with, six ounces should be taken three times daily, and this may be gradually increased to eight or ten ounces. How it acts we do not, of course, know. Professor CARSON was wont to ridicule the idea of sarsaparilla purifying the blood, because he laughed at the idea of the *blood becoming impure.* Whether he was right or wrong we will not judge, but we can say positively that compound decoction of sarsaparilla is a very valuable remedy in syphilitic cachexia.

Not only will this decoction be found useful in the condition indicated, but it has also been frequently found beneficial in those indefinite conditions of ill health when no particular disease can be said to exist and yet the individual is not well. It has been found useful in the frequent slight derangements of the aged. and will relieve that condition of malaise so frequently supervening upon imprudence and excess in eating or drinking long continued, but where it has not yet produced any definite disease.

SCHOOL BUILDINGS.

From a report of the Board of Education of Cleveland, Ohio, we are glad to note that the sanitary construction of school houses is about to claim the attention that it deserves. Too much care cannot be bestowed on this important point. When we reflect that the majority of children spend the greater portion of their early active lives in school, it will be evident to all thinking men that these buildings should be so constructed as to remove all possibility of disease from bad sanitary arrangements. The majority of our private school buildings, in this portion of the country, are old; they were built at a time when but little thought was given to hygiene or sanitary science; hence, while fairly well constructed, they lack, at least the majority of them do, the appliances for preserving health that our latter-day acquaintance with sanitation renders possible. Our public school system in Philadelphia is one of our prides, and is excellently well organized; the buildings are large, handsome and commodious. But in some features they lack the very points toward which the Cleveland School Board are directing their attention. For one thing, they are very high, three and four stories. The Cleveland Board recommends two-story buildings. In order to carry out their reform, they have addressed a circular to architects, offering a premium of five hundred dollars for the best plan of a two-story school house, based on sound sanitary principles. For their guidance the following points are mentioned:—

1. Rooms of size to afford fifteen square feet of floor per pupil, that is, nine hundred square feet for about sixty pupils.

2. Window space not less than one-fourth of size of floor.

3. Height of room not to exceed fourteen feet.

4. Ventilation to introduce not less than thirty cubic feet of fresh air for each pupil per minute, and remove an equal amount of foul air, from the level of the floor.

5. Heating arrangement so connected with ventilation as to secure even temperature, that shall not differ materially in different parts of the room, and air to so enter as not to expose any of the pupils to unwholesome drafts.

6. Water-closet accommodation to be abundant, well ventilated, and the building thoroughly secured against sewer gases.

Realizing how readily inherited diseases lying dormant in the system may be roused into future activity by unhealthy conditions and surroundings in school, this action sets a good example, that all cities will do well to follow.

In Boston an active effort, with good prospects of success, is being made to secure sanitary inspection of schools. It cannot be too frequently urged upon the public, by physicians, that prevention is infinitely cheaper and much more satisfactory than cure. The large majority of human beings know but little and care less about hygiene. They regard it as a science beyond their comprehension, and pass it by. They should be taught that while the more intimate minutiae of sanitary science require, for their proper understanding, some knowledge of the science of medicine, yet there is a great deal that they can understand and that they ought to know. It will be much more satisfactory, in the long run, if, by proper precautions, children are kept healthy, than it will be, if by neglect of them they grow into semi-invalid men and women, burdens to themselves and to others.

PROFESSIONAL LIBERALISM.

View it as we may, there can be no doubt that in ethics the profession of medicine is much less conservative than it was a few years ago. Progress is so gradual that those who live during a period of changes fail thoroughly to realize them, since they come one by one, allowing time for custom to breed familiarity with the first before the second follows on its heels. If, on the other hand, the spirits of Astley Cooper, John Hunter, Chapman, Dewees, Jackson, and Physic, could return for a short time to their ever remembered localities and duties, think for a minute what they would see. Their eyes would become round with amazement, as they read of the utterances of distinguished English physicians, in favor of admit-

ting homœopaths to their consultations. They would see the wife of the distinguished editor of one of our greatest journals herself a distinguished and cultivated physician. They would stand aghast when they heard that the medical profession of one of the greatest States in the world had rendered it officially proper to consult with a sect, the members of which they, in their day and time, avoided and shunned, professionally, with as much or even more care and assiduity, than they did the devil himself.

They would find physicians in good standing officiating as teachers in medical colleges for women. They would be informed that several medical societies of repute had opened the door of membership to female physicians. In time their unsophisticated minds would awaken to the various devices used by their modern confreres to secure practice, and they would be almost paralyzed when they learned how much wire pulling and political intrigue had entered into their beloved profession.

We do not mean to say that this is not all right. We are champions of progress, and rejoice when we see human nature advancing. We merely desire to enable our readers to enjoy with us the real amusement that would be afforded by the puzzled and half incredulous expression that would occupy the faces of these old medical war horses were they enabled to see and hear what we do, and to watch them throw up their hands in astonishment, as they exclaim, "*By the shade of the great Hippocrates, but this is an age of progress,*" as they vanish from sight into the dim mist of uncertainty, born of their doubts as to whether all this seeming progress will redound, in the end, to the real and substantial advantage of their ancient profession.

Notes and Comments.

Cucumber or Carbolic Acid.

The *British Medical Journal* says: America is suffering in a very marked degree from the pollution of drinking water, which is so apt to be the Nemesis of the accumulation of great city populations, unless primary regard be paid to scientific sanitation, and especially to the supply of pure drinking water, as well as the preservation of purity in the soil and air. The drinking water of the great cities of America appears to be in some instances little better than sewage water, and in numerous cases the pollution of potable water in great cities is such as to cause, at the present moment, considerable disgust on the part of city residents, and to call for government intervention, which is unfortunately slow, and not always satisfactory in its action. From comparative results which have been published by Dr. A. R. Leeds, in the *Chemical News*, it would appear that the water at Newark, Jersey City and Hoboken had become suddenly noticeable for the highly marked flavor of carbolic acid, indicating that the pollution of that particular water supply was at that moment of an especially chemical nature. When the board was made aware of the nuisance, it was ingeniously urged that water was all the better for being polluted with carbolic acid, inasmuch as it served to disinfect the other kinds of filth which got into the drinking water. This plea, however ingenious, was not held to be good in law, and so, for the moment, the inhabitants of Newark, Jersey City and Hoboken have to drink their potable water without the preliminary disinfection, which made it more unpleasant to the taste, if less noxious to health. Boston is suffering from what is described as a striking and interesting and scientific peculiarity. Its drinking water shows albuminoid ammonia to the extent of 0.0605, a statement which analytical chemists and medical officers of health will read with grim surprise. It is stated, however, that the peculiar interest is, that this is due, first, to the pollution by a few manufacturing towns, and, secondly, to the growth of algæ. There is especially an extremely interesting and rare freshwater sponge, *spongilla fluviatilis*, which accounts for the peculiar "cucumber taste." It is thought that the Boston people would be more reconciled to the "cucumber taste" if they took a little more scientific interest in the *spongilla fluviatilis*, which is accordingly elaborately described and figured, and recommended as an object of interest under the microscope. Another source of pollution of the Boston water is Pegan Brook, which flows through a town of ten thousand inhabitants, almost entirely engaged in the dressing of leather and manufacture of shoes; the outflow from which factories is supposed to complicate the "cucumber flavor." Philadelphia and New York also, it appears, receive their water from polluted sources. The feeders which empty themselves into Croton Lake, the

principal reservoir of the New York water, pass through a settled country, with numerous tanneries, factories, etc., along their banks. Wilmington, Del., also ranks among the towns supplied with polluted water. Under these circumstances it is satisfactory that an energetic effort is promised to maintain the public interests and to protect the public health by improving the sources of water supply, and guarding them against contamination; and, meantime, it is not surprising that Apollinaris water is stated to have become so general a favorite in the United States, that its consumption there as a daily table water equals that of Great Britain.

Headaches in Children.

Dr. Day read a paper on this subject before a recent meeting of the Harveian Society, of London (London *Lancet*). He alluded to the two great causes of headache, from a pathological point of view, viz: cerebral anæmia and cerebral hyperæmia. He said that habitual headaches in children indicate an irritable and exhausted brain, and if intellectual exertion be carried too far in such cases, mischief is soon likely to ensue. If intellectual exertion be carried beyond a certain point, the brain becomes anæmic, fatigued, and the nutrition in the ganglion cells of the cortex becomes impaired, diseased, or in some way altered from health. The author referred to neuralgia, or one-sided headache, which he said was more common in children than was generally supposed. He had known headache in connection with chorea and dental caries. Dr. Cheadle considered foul air and gas were the chief causes of study-headache; he referred to headaches in rickety children. This occurred just after the skull closed, was continuous, but gradually subsided. Dr. Mackenzie particularly insisted on the importance of careful examination of the eyes in cases of headache of children. Muscular asthenopia was a cause of headache which sometimes was mistaken for serious organic disease. He mentioned the case of a schoolboy brought to him under this supposition, but myopia was found and corrected, and the headache disappeared. The same thing occasionally occurred with hypermetropia. Next he pointed out that ear disease was sometimes the cause of headache; which is important as significant of commencing meningeal or cerebral inflammation. In all cases, therefore, of headache in children, it is very important to examine the ear and the eye, using the ophthalmoscope, which will be of great value in detecting organic disease. He remarked that pain in the head, a valuable sign of tumor of the brain, was no certain indication of localization of the tumor, unless there was corresponding pain on percussion. The President, in conclusion, said that headache, though not a common symptom in children, was one of import, and frequently indicated advanced disease.

Acute Farcy in Man.

At a recent meeting of the Pathological Society of London (*Medical Times and Gazette*), Dr. Howard Bendall said this was the case of a healthy man, who was inoculated from a horse suffering from farcy. When first seen he was suffering from multiple abscesses, which were chiefly situated in the neighborhood of the joints. Shortly afterward the characteristic pustular eruption appeared on the skin, and signs of pneumonia supervened, accompanied by dyspnœa. The dyspnœa rapidly increased, and the patient died comatose. The objects of chief interest at the autopsy were the lungs. These were both deeply congested, the left lung showing, in addition, extensive lobular pneumonia of the left base. Microscopically, the lungs were crowded with fatty emboli; hence the intense dyspnœa. In addition to this, the pus from the abscesses was found to contain free oil in considerable quantity, while sections from the neighborhood of the ulcers on the skin and mucous membrane showed the tissues to be in a state of rapid necrosis, in which almost all the cell elements had disappeared. The tissues in these parts were loaded with amorphous fat granules, of all sizes. Dr. Coupland had seen a similar case about ten years ago. Dr. Bendall called this case "farcy," because the nasal symptoms came on early, and were the most marked feature of the disease.

Pregnancy Complicated with Epithelioma.

At a recent meeting of the Obstetrical Society of London (*Medical Times and Gazette*), Dr. Edis asked for an expression of opinion on the following case: A woman, aged twenty-nine, married seven years and nine months, mother of one child eighteen months old, came as outpatient, on account of pains and sanguineous discharge, and was found to be six months pregnant. The whole of the cervix, and the posterior wall of the vagina down to within an inch and a half of the perineum, was affected with epithelioma. The cervix was dense, nodulated, rough, but did not bleed very readily. The whole disease

could not be removed by the Porro-Freund operation, and the question was whether to induce premature labor, or to let the patient go to term and perform Cæsarean section.

Dr. Wiltshire thought that if the disease had extended down the posterior vaginal wall nearly as far as the perineum, Porro's operation would fail in removing it. He mentioned a case of excessively dense cancer of the cervix, in which he preformed Cæsarean section, some years ago, but in which Porro's operation would have been admissible had it been then in vogue.

Dr. Herman said that published cases showed that the consistence of the growth was of more consequence, as regards delivery, than its extent. Living children had been borne after quick and easy labors, although the whole circumference of the cervix and vagina was cancerous; and, conversely, cancer of small extent might, if very hard, cause great obstruction.

Dr. Priestley agreed with Dr. Herman, that the consistence of the growth was of most importance. He did not think the case suitable for Porro's operation, as the child was not viable at the sixth month, and the mother's life could hardly be prolonged by it. He would chiefly regard the child's life, and would be disposed to let the woman go to full term, or nearly so, and then act according to the amount of obstruction found to exist.

Iodine in Typhoid Fever.

Dr. N. S. Davis, in the Chicago *Medical Journal and Examiner*, says, "To more effectually counteract these morbid changes (in typhoid fever) we need some remedy capable of exerting a general alterant and antiseptic influence, and maintaining it for a considerable time without depressing the strength or creating local complications. The last time I took you to the bedside of typhoid fever patients, I called your attention to the effects of iodine, which I had then commenced giving. Since then I have continued to use the remedy in all well marked cases of typhoid. I have now used it in fourteen cases. Nine of this number were brought under treatment during the first week of the disease; the other five not until the first half of the second week. The treatment in all consisted in the administration of from 12 to 15 minims of the following solution of iodine:—

℞.	Iodinii,	gr. viij
	Potassii iodidi,	gr. xxx
	Aquæ destillatæ,	f℥ iss. M.

"The dose was generally diluted with two tablespoonfuls of sweetened water, and repeated every four hours, for the first three or four days, and then every six hours until indications of convalescence appeared. From my present experience I am led to think it is a remedy of great value, especially when its use is commenced in the forming stage, or during the first week after the confinement of the patient from the development of the fever. I am not using iodine as a *specific* curative agent in typhoid fever, but simply as a general alterant and antiseptic, adapted to fulfill certain rational indications afforded by the pathology of the disease, and always to be aided by such collateral remedies as the abdominal or other local symptoms may indicate."

Genital Irritation.

At a recent meeting of the New York Neurological Society (*American Journal Neurology and Psychology*), a paper entitled "The Effect of Genital Irritation in the Production of Reflex Nervous Symptoms" was read by Dr. L. C. Gray, of Brooklyn. His conclusions were as follows:—

1. That there is no proof that genital irritation can produce a reflex paralysis.

2. That while it is probable that the slight nervous disorders, as incontinence, retention, difficult micturition, erratic movements, and slight nervous disturbances, can be produced by genital irritation, the proof is not yet complete.

3. That operations for the removal of genital irritation may be beneficial even in organic nervous disease.

4. That we should, therefore, remove such genital irritation, if it exists, in any case whatsoever, and thus give our patients the benefit of the doubt.

5. That in all cases of nervous disorders, with accompanying genital irritation, we should not regard the latter as the cause of the former until all other probable or even possible causes have been rigidly excluded.

6. That operations upon the genitals, even when there is no genital irritation present, may prove to be a useful therapeutic measure in certain cases.

Ergot for Enlarged Spleen.

Dr. W. E. Manuel contributes the following case to the St. Louis *Courier of Medicine*. He was called to a gentleman 43 years of age, with an enlarged spleen, covering nearly the entire abdominal cavity and extending as far back as the border of the liver.

Two weeks before the spleen had commenced to enlarge. It was very firm, hard and painful. No malarial origin of this enlargement could be discovered. He was very much reduced in weight and extremely weak. He was also suffering with nephritis. The urine was of a dirty, brownish appearance, filled with sediments, the chief of which were phosphates and urates, while it was loaded with albumen. Subsequent events proved that the pressure of the enlarged spleen accounted in a certain degree for the albuminuria. The treatment was commenced with thirty minim doses of Squibb's fluid extract of ergot, three times a day, to be gradually increased until the dose reached sixty minims. In three days the spleen had lost a great deal of its hardness and was flabby to the touch, though not noticeably reduced in size. In one week there was a perceptible diminution, and from that time, day by day, he could perceive a marked diminution, until it has now returned to almost its normal condition. With the reduction of the spleen, the kidneys became decidedly better, the albumen almost entirely disappeared, and with buchu, uva ursi, and copaiba, taken as the spleen reduced, his urine began to clear up.

Poisoning by Yellow Aconite.

The *Medical Times and Gazette* has the following: "A lady had a bunch of freshly cut flowers of the yellow aconite in a glass of water on the table in her drawing room; a pet dormouse belonging to one of the children was running about on the table, over the child's hand and arm. The child said the dormouse was thirsty, and she took her little thimble, filled it with water from the glass, and offered it to the dormouse. The animal drank it readily. In a minute or two it fell over on its back; and after a short struggle, died on the table." The yellow aconite would thus seem not to be quite so inactive as has been assumed.

Hypnotism.

The Paris special correspondent of the *Lancet* says: M. Milne-Edwards, the president of the commission appointed by the Academy of Sciences to report upon M. Dumontpallier's experiments on hypnotism, read a short note on the subject, which will probably bring the inquiry to an abrupt termination. He stated that Professor Harting, of Utrecht, had communicated to him the results of similar experiments made on rabbits, fowls, guinea pigs, pigeons and frogs. The six fowls submitted to hypnotism on several different occasions died of paralysis. M. Milne-Edwards announced that he would carry out analogous experiments at the Jardin des Plantes, but that they must be considered as too dangerous to be performed upon human beings, without considerable circumspection. M. Vulpian had already marked his appreciation of this kind of inquiry by withdrawing from the commission. Whether there is really any immediate risk to a hysterical girl from the treatment she receives in a Paris hospital may be open to doubt, but there can be no question that, in the long run, it is extremely injurious.

Nasal Calculi.

In our issue of March 11th (on page 271) we offered a note on this subject, from the St. Louis *Medical and Surgical Journal*. From a subsequent issue we notice that Dr. Porter stated to the St. Louis Medical Society that he knew of a most interesting specimen, a foreign body, which was removed from the nose of a gentleman of that city. He had chronic discharge from the right nostril, and had been well treated by others, and when examined it could not be ascertained why he did not get well; but on watching the case a little further, it was found not to respond to the usual methods of treatment. One day he discharged from the antrum (there was no doubt of the locality), a little mass which was found to be an embryonic tooth that had been pushed into the antrum, and had doubtless remained there many years. This gentleman said that he had this discharge from boyhood, and was 38 years old. The discharge of this foreign body completely relieved him.

Foreign Bodies.

In a recent issue we noted a case in which a grain of corn was discharged through the chest; commenting on this case Dr. Wilks, President of the Pathological Society of London (*Lancet*), recently read a letter from Dr. Francis Darwin, stating that he knew of horns of grass and corn which had pierced the various organs and parts of animals. In South America a grass-seed works its way right through the skin of the sheep. In Australia the fruit of a grass works its way through the chest and abdomen of animals, and into the heart, lungs, liver and kidneys. These two grasses are adapted to working down into the ground under changes of temperature and moisture. The horns and barbs on the ear of corn in Dr. Wilks' case are directed backward, and therefore any movement forces it on, and cannot make it recede.

Special Reports.

NO. V.—OPHTHALMOLOGY (Continued).

BY CHAS. S. TURNBULL, M.D.

On the Extraction of Cataract—Knapp's Modification of Graefe's Peripheric-linear and Wecker's Flap-section, with Peripheric Capsulotomy and Subsequent Discission of the Capsule.

Both observation and experience induce us to recommend what is known as "Knapp's modification" of the operation for the extraction of cataract,* and, as we consider his method of sufficient interest and importance, we quote his own words and describe the details of the operation somewhat at length, in the hope of tempting the more progressive, and especially the younger, members of the profession to give this method a fair trial, with the full assurance that it offers more advantages and less disadvantages than any other, and, on the basis of statistical data, claims a peculiar influence on the final object of all operations for cataract—the restoration of sight.

In a recent lecture† Knapp makes a synopsis of *thirty extractions*, which serve as a basis for the following remarks, in the course of which he describes in detail the steps of his operation; and we have added cuts of most of the instruments he employs:—

"The *youngest* patient was a servant girl, aged thirty-two years, whose cataract I would, under ordinary circumstances, have operated on by division, but as she was blind in both eyes, had only recently come to this country, and was without support, I preferred that operative procedure which restored her sight in the shortest time. There were three patients between forty and forty-eight years of age; the remainder were over fifty. The oldest was eighty-two.

"The *method* was a *more or less linear or low-flap section, with a broad iridectomy, and peripheric opening of the capsule.* In the first operations (Fig. 1), Graefe's section begins and terminates one millimeter in the corneo-scleral junction, its apex being at the transparent margin of the cornea, or even one to two millimeters below it. Gradually I shifted into the flap-section (Fig. 2), which De Wecker, of Paris, recommends as the best, namely, a section with a Graefe's knife, situated exactly in the transparent margin of the cornea, extending over its upper third.

Fig. 1.

Fig. 2.

For full-sized cataracts, I made it somewhat larger. Both sections—the linear and the flap—have their advantages and their disadvantages; the linear does not incline to tilting, and shows a very accurate coaptation, but as its ends are nearer to the insertion of the iris, it is more liable than the flap to adhesions and incarcerations of the iris and to cyclitic processes. With regard to firm closure of the wound, one of the most important factors in the whole operation, the flap, though easily gaping during the operation and soon after it, has one redeeming quality—it cuts the lamellæ of the cornea obliquely, not at right angles, as the linear section does. This principle of oblique piercing is frequently made use of, and with admirable ingenuity, in the animal organism. Let me only mention the ductus choledochus piercing the wall of the duodenum obliquely, by which contrivance the bile can, without obstacle, flow into the gut, but the food, while passing from the pylorus onward, will press the inner wall of the valve-like opening of the bile-duct against the outer, and thus completely close the aperture. Somewhat in the same manner the inner lip of the flap-section is pressed against the outer by the contents of the globe, whereby a firm and lasting closure may be established. Theorizing is a fine thing in its way, but worthless without the test of experience, because in complicated problems we commonly fail to know and appreciate the quality and quantity of all the coöperating factors. Wecker's section has thus far shown us very kind healings, encouraging to further trial."

The most approved form of speculum, *i. e.*, Graefe's modified, is shown by Fig. 3. The arms are curved so that the loop of spring and adjusting screw are out of the operator's way. There is a right and left speculum. Fixation forceps by Fig. 4, and a typical Graefe's cataract knife, by Fig. 5.

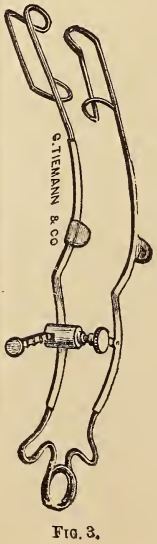

Fig. 3.

Fig. 4.

Fig. 5

* Knapp's previous report of a hundred cases of extraction (the sixth hundred), published in the July number, 1879, of the *Archives of Ophthalmol.*, refers to 66 successive cases of extraction with peripheric capsulotomy, and, together with the preliminary communication in Vol. VI, and later in Vol. X, No. 3, contains the substence of his views and experience on this subject, also historical and critical remarks on the peripheral opening of the capsule.

† On the Extraction of Cataract. By Herman Knapp, M.D. The *Medical Record*, New York, Feb. 18th, 1882.

"The *iridectomy* in almost all of our operations was large. The coloboma varies from $\frac{1}{3}$ to $\frac{1}{4}$ of the corneal circumference. When the corneal section and the opening of the capsule are peripheric, it must be large, or the columns of the coloboma will be an obstacle to the exit of the lens, which, if overcome by force, entails bruising and incarceration of the iris. When the iris is being cut, it ought not to be dragged with the iris forceps (Fig. 6) into the corners of the section, since there the lips of the

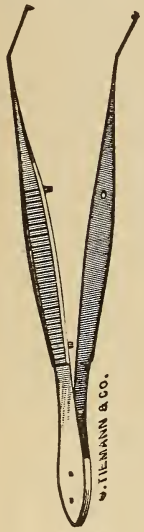

Fig. 6.

Fig. 7.

wound act like clamps, holding the iris-tissue tight between them. It is good practice to seize the iris in the centre of the section, draw it straight up and cut it off close to the cornea—carefully avoiding the corneal tissue itself—in one, two, or three strokes of the iris scissors (Fig. 7), as may prove convenient, and afterward, according to the sufficient or insufficient size of the coloboma, either reduce or exsect iris tissue which may still lie in the corners. Such tissue, even after a clean and apparently satisfactory iridectomy, remains hidden in the wound more frequently than we imagine. Proofs: 1. The anatomical examination of eyes on which iridectomy had been made for glaucoma, or combined with cataract extraction, commonly found the stump of the iris or its adjacent tissue united with the corneal scar, even if no outward inspection could discover such a condition. 2. Many times, when passing the cystotome from the corners of an apparently unobstructed corneal section toward the centre, I drew iris-tissue along, which was either the periphery of the adjacent iris, or the stump of the part which had been removed. Such portions, of course, have to be grasped with the forceps and cut off. This observation has taught me not to rest satisfied with an apparently correct coloboma, even if its sphincter edges are in the anterior chamber, but, before opening the capsule, to clear the whole extent of the corneal section, especially the corners, of iris-tissue, which, with a delicate probe or spatula, may be stroked back into the anterior chamber."

"When the wound is clean the operator takes the fixing forceps in his own hand, presses gently with it on the globe, so as to make the corneal section slightly gape, and *passes the needle cystotome* (see Fig. 8) *from the inner corner of the section to the outer, through the anterior capsule of the lens.* This manœuvre has to be closely watched; a far-sighted operator should make himself near-sighted by convex spectacles, and either daylight or artificial light ought to be thrown on the eye by a large convex hand-lens, so that the point of the cystotome can be accurately followed in its course through the capsule. An insufficient capsulotomy is commonly without consequences, as the cataract on its way out enlarges the opening; only in tough capsules it is an obstacle to the expulsion of the lens, and may lead to prolapse of vitreous. When I had practiced this mode of opening the capsule in about two hundred cases, I varied it, not because I was dissatisfied with its results, but in order not to get wedded to one particular procedure. There is no conceivable way of opening the capsule that has not here and there been tried. The one just described is the simplest in execution, and the least injurious to the eye, but it has the disadvantage of necessitating, in the majority of cases, an after-operation, viz: the subsequent central splitting of the capsule. In order to avoid that, I have lately joined to the horizontal division a larger vertical one than I made a few years ago while practicing a T-shaped opening. A *bent needle cystotome* (Fig. 10) is introduced into the anterior chamber, and the capsule slit open from the lower edge of a middle-wide pupil, up to the centre of the corneal section. In order not to let the outcoming lens enlarge the upper end of the capsular wound irregularly, I made the horizontal incision in one case with a delicate, sharp-pointed scalpel, the point of which was inserted into the upper end of the vertical incision of the capsule at the centre of the corneal section, pushed forward toward one corner of the wound, and then, by raising the hilt, one-half of the upper margin of the capsule was ripped open. In the same way the other half was dealt with. In another case I made the horizontal incision of the capsule with the needle cystotome, which was passed first from one, then from the other corner of the corneal section through the capsule, so as to meet the upper end of the vertical capsular section. If the cystotome were passed

Fig. 8. Fig. 9.

Fig. 10.

from one end of the section to the other, it would split the first half of the capsule, but most likely not the second, for when fallen into the vertical section, it would enlarge this by dragging the capsule before it rather than cut it. The few cases thus operated on did well; the first one showed some transient adhesions of the iris to the shreds of the capsule. It remains to be seen whether a greater number of cases will yield as smooth recoveries, and better permanent vision than the other now well tried method.

Fig. 11.

"The *expulsion of the lens* is effected by pressing with a hard rubber spoon (Fig. 11) on the lowest part of the cornea.

"The *after-operation*, the subsequent central division of the capsule, is an essential feature in this mode of operating for cataract. Without it the method could not stand, as it has also virtually been abandoned by the operator who first, in 1873, tried it on a larger scale, namely, Professor Gayet, of Lyons. He made no after operations, and was dissatisfied with the imperfect visual results. The empty capsule will wrinkle and opacify, requiring subsequent splitting, in the majority of cases. But then, the visual results are permanently good, and better than by any other method, except the removal of the lens within the capsule, which, according to its warmest advocate, Dr. Herman Pagenstecher, is indicated in thirty per cent. of the patients only.* But do the methods with central opening of the capsule, even in their successful cases, commonly yield good vision permanently? By no means. With them, too, the capsule will wrinkle and opacify, and vision be reduced to a surprising degree.

"The subsequent division of the capsule comprises not only its anterior, but also its posterior half, and, therefore, gives a perfectly unobstructed pupil. The imperfect visual results, after the primary central division of the anterior capsule, have always been felt by the profession, and given the incentive to different attempts at obviating this disadvantage, among which I will mention the puncture of the vitreous, immediately after the expulsion of the lens, which Professor Hasner, of Prague, has made for many years, and which, as I saw last summer, has been adopted, on trial at least, by Schweigger. Both gentlemen assert that this procedure is not dangerous, but neither has, as yet, published statistics to convincingly support their assertion. The subsequent division of both capsules is an innocent operation; I have done it more than a hundred times. Only in a few cases the reaction from it lasted longer than a few days, and never was the vision made worse. The technique of the operation, however, is peculiar, and has to be learned. The operation requires, above all, two things, without which nobody should undertake it: first, *good artificial light*, thrown on the eye with a large lens, so that during the operation every wrinkle, dot and stria of the capsule can be seen, as well as the course and effect of the needle; second, a *sharp, well-proportioned scalpel needle** (see Fig. 9), with which the capsule can be cut without tearing. I first make a horizontal incision, then a vertical one, varying them, however, according to the conditions of the capsule. No aqueous should, none need escape. I have described it in the *Archives of Ophthalmology*, Vol. VIII, No. 2, p. 200, Vol. X, No. 3, p. 295.

"Now, in conclusion, a word or two on *antisepsis in cataract operations*. I have never thought much of the specifically antiseptic *substances* which ophthalmology has recently borrowed from general surgery, and I cannot yet see any reason to change my opinion. If the adherents of the antiseptic method affirm that this essentially consists in the careful observation of all the rules that secure or at least favor union by first intention, they have no warmer friend than me. Those rules are no modern revelation, and in no operation have they been more carefully studied than in the extraction of cataract. If, however, antisepsis means "bacteria-killing"—to express it in one word—and its advocates assert that all their methods and antiseptic substances employed before, during, and after the operation have this fundamental aim and object, then I think they hunt a phantom. I am far from denying the existence of micrococci and bacteria; they are on and in all open, moist tissues, though the conjunctival sac shows them less than most other places (see Wernich's instructive book, "Die Desinfectionslehre"). I do not, of course, deny the existence of infectious substances, such as blennorrhoic, even dacryocystitic, and similar secretions, as well as decomposed and fermenting bodies; but, gentlemen, these substances are but *one group of irritants*, which, as all the others, ought carefully to be guarded against. Besides them, there are plenty of mechanical and chemical irritants, which have equal claims on our consideration. The great modern dictum, "No suppuration without bacteria," which was until quite recently ardently defended, has proved untenable; even its most zealous advocates had to concede that croton-oil and other substances produced suppuration, without any coöperation of bacteria. One of the latest investigators of this subject, Dr. N. Uskoff, answers the question whether or not suppuration is possible independently of low organisms? positively in the affirmative (*Virchow's Archiv*, vol. lxxxvi, p. 150, etc., October, 1881), and does so, not from theoretical speculation, but based upon numerous experiments made by him and Professor Ponfick, at the Pathological Institute of the University of Breslau. Lister himself, in closing the discussion on this subject, at the last International Medical Congress, said: "Solid bits of dirt are the great sources of danger, rather than certain invisible particles that float in the air, and have, perhaps, been invested with more deleterious functions than they really possess" (*British Med. Jour.*, October 1st, 1881, p. 550).

* On the Extraction of Cataract in its Capsule. By H. Pagenstecher, M.D., of Wiesbaden. *Archiv. f. Ophthal.* Vol. VIII, p. 243, Vol. X, p. 152.

* Reliable needles of this kind, as well as the other instruments, are made by Tiemann & Co., New York.

"The antiseptic methods which have conquered, for good reasons, the greater part of the surgical world, have also many adherents among the first names in ophthalmology. I will mention to you only Wecker, Horner, Snellen, Leber, H. Pagenstecher. Alfred Graefe, whose early paper on the subject, in Graefe's *Archives*, has made so many converts, had the mortification to see that the good results, not to say the good luck, which had attended his earliest antiseptic procedures had unaccountably deserted him later, so that he is said to have become skeptical. Horner stated, in London, that, apart from antiseptic precautions, success depended upon the most delicate execution of every step of the operation. Now, what has *experience* to say on the question of antiseptics in ophthalmology? Where are the all-important statistics to support it? They have not yet come forward. The best operators, *e. g.*, Wecker and Horner, still concede one per cent. to two per cent. of total loss by suppuration. This is a less percentage than the old flap showed, but not less than is obtained by a careful execution of Graefe's extraction, without antiseptics, and the results in this institution, for years, have been no worse. There were two cases of suppuration in the last hundred extractions I reported on. Since then, March 3d, 1880, fifty-two extractions were performed, without the occurrence of suppuration, even without the loss of an eye from any cause. Several larger series of operations, performed under antiseptic precautions, have been published (Just, Reymond and others) which are quite unfavorable. Yet this subject is still under discussion, and, though I am not prejudiced in favor of the bacteria killing contrivances, I shall not tire in giving the question how to secure healing by first intention, how to avoid inflammation in general, my undivided attention. In order not to judge of the subject without personal experience, I shall continue to give antisepsis a fair trial, until facts sufficiently numerous pronounce their unambiguous verdict. Every alternate operation in the thirty cases which were witnessed, and which were the basis of these remarks, was performed under antiseptic precautions. Though I shall have to return to this subject later, I may here state that a difference in the course of healing has not been apparent, and, if asked my candid opinion, I would say that the best antiseptic is twenty years' experience."

That we may do full justice, we quote from no less distinguished an authority than Dr. Herman Pagenstecher (*loc. cit.**) who advocates the *operation of extraction of all mature cataracts in their capsule*, and says, "Indeed, I go so far as to say that we make a great mistake—will the older operators pardon my expression?—when we operate on cataract after irido-choroiditis, or on hyper-mature, or Morgagnian cataracts, in any other way than by extraction in the capsule." He at the same time, by calling attention to an old and well established ophthalmological fact, says he lays down one important rule, which, nevertheless, will bear constant repetition, *i. e.*, "cataracts which have matured rapidly, say in the course of a few months, should never be removed in the capsule, but always by opening the capsule. In some cases the capsule does not obtain sufficient strength in comparison with that of the zonula."

"One reason why (says Pagenstecher) this method has been so little employed is, that every one likes to continue with the operation which he first learned and practiced, and which has probably, so far, given satisfactory results; secondly, everybody imagines that it is a violent procedure to pass the flat spoon into the eye, for the purpose of removing the lens. Then it is a common opinion that loss of vitreous endangers the eye; further, we are told that we are never sure of removing the lens with the whole of the capsule; and, finally, many have never seen the operation, and hence have had no chance for deciding upon its merits from their own knowledge.

"In the first place, it is necessary for us to be sure what cases are to be operated upon by extraction in the capsule, and what cases are not. Our own (P. and his brother, the late A. Pagenstecher) observations, combined with a moderate degree of attention, soon throw light upon this point, and he who at first only ventures to employ the operation in the cases where it is undoubtedly the best, such as cataracts after irido-choroiditis, pronounced hyper-mature cataracts and Morgagnian cataracts, will soon gain more and more confidence in the operation, and discover for himself in what further series of cases it is indicated."

Comment is unnecessary upon this method of extraction of the lens within the capsule, which, says Knapp, "is, according to its warmest advocate, Dr. Herman Pagenstecher, only indicated in thirty per cent. of all cataracts."

*Translated by James A. Spalding, M.D., Portland, Maine.

Correspondence.

Obscure Cases.

Ed. Med. and Surg. Reporter:—

A bright little girl, 11 years old, had a sore throat for a few days and a stiff neck for a fortnight. At this time I first saw her, on washing day, when being up and around she evidently took more cold, and all symptoms were much aggravated except sore throat. Left side all right. Right sterno-mastoid and gland at angle of the jaw much swollen, and also the tonsil and root of tongue, swelling extending up to right eye. Head turned to left and held in constrained position. Voice almost extinguished. Swallowing

difficult, not from soreness but from swelling. Examination of throat impossible. This was on Monday. At my visit on Thursday, found that in previous night something had broken, and patient was spitting bloody pus, with much relief. On Friday better. Did not see her again until Monday, when symptoms were worse. Quick pulse, more fever, pain and tenderness of legs, but no swelling, pupil of right eye much dilated. During night had spit up more bloody pus. While reporting to the mother Watson's case of quinsy the patient cried out, "It is coming," and immediately threw off a large quantity of bright blood. Inspiration drew some into the lungs, and in one or two minutes a general convulsion ended the scene. What was it? Who has seen the like? What could have been done?

Case 2.—A married woman, aged 31, arose in the morning in usual health, prepared breakfast, and was taken with a "fainting fit." On the previous evening had taken a small dose of castor oil, for constipation and piles. After two hours I found her in complete collapse; very pale, cold sweat, no pulse at wrist, heart beat slow, feeble, but not abnormal. Great pain at epigastrium. Lay on left side and could not turn on to the back. Had missed two menstrual periods and been suffering a long time with leucorrhœa, but without treatment. Had been pregnant only once, and miscarried at three months. Seemed like one suffering severe hemorrhage; mind all right. Ventured a diagnosis of extra-uterine pregnancy or perforating ulcer of the stomach. Brandy failed to rally her, and she died at 4 P.M. same day. Autopsy showed two quarts of blood in the abdominal cavity, and great enlargement of left Fallopian tube, which had ulcerated and showed an opening the size of a dime, its inner surface lined with coagulated blood. The left ovary had developed a serous sac as large as an ordinary hen's egg. There was also a smaller cyst in right broad ligament. These two cases happened within three months, in an ordinary country practice. S. L. Chase, M.D.

Colchester, Conn.

News and Miscellany.

COMMENCEMENTS.

Jefferson Medical College.

The Annual Commencement of the Jefferson Medical College was held in the Academy of Music, on Thursday, March 30th. The ceremonies commenced with prayer by the Rev. I. L. Nicholson, after which the degree of Doctor of Medicine was conferred upon 247 graduates. The degree of D. D. was conferred upon Rev. I. L. Nicholson, of St. Mark's P. E. Church, and Rev. Charles Maison, of St. James P. E. Church, Kingsessing. The degree of LL. D. was conferred on Dr. Thomas Addis Emmett, of New York. The prizes to the graduates were awarded as follows:—

1. A prize of $100, by Henry C. Lea's Son & Co., for the best Thesis, to Samuel O. L. Potter, of Wisconsin; with honorable mention of the Theses of Charles Meigs Wilson, Hiram R. Loux, and Horace G. Hill, of Pennsylvania; and Henry B. Fergerson, of North Carolina.

2. The "Robley Dunglison Prize" of $50, by Dr. Richard J. Dunglison, for the best research in Physiology, to Edwin Bergstresser; with honorable mention of the Thesis of J. Edgar Belville, of Pennsylvania.

3. A prize of a Gold Medal, by R. J. Levis, M.D., for the best Report of his Surgical Clinics at the Pennsylvania Hospital, to Henry E. Everett, of Pennsylvania; with honorable mention of the report of A. Bern-Hirsch, of Pennsylvania; J. Augustin Herrero, of Porto Rico; and Richard Douglass, of Tennessee.

4. A prize of a Gold Medal, by Thomas G. Morton, M.D., for the best report of his Surgical Clinics at the Pennsylvania Hospital, to Edwin Eareckson, of Pennsylvania; also, a second prize of a work on Surgery, to David H. Melhorn, of Pennsylvania.

FACULTY PRIZES.

5. A Case of Instruments, for the best Essay on a subject pertaining to Surgery, to William Niles Powell, of Pennsylvania; with honorable mention of the Theses of John Franklin Foulkes, of California; James E. Baker, of Wisconsin; and Edwin B. Mathiot, of Pennsylvania.

6. A Case of Instruments, for the best Essay on a subject pertaining to Obstetrics, etc., to Charles L. Whitfield, of Texas; with honorable mention of the Theses of John B. Mahon, of Pennsylvania; and Luigi M. de Jesi, of Italy.

7. A Gold Medal for the best Essay on a subject pertaining to the Practice of Medicine, to Herbert M. Seem, of Pennsylvania; with honorable mention of the Theses of Louis W. Atlee, of Pennsylvania; and Frank E. Wilson, of New York.

8. A Gold Medal for the best Anatomical Preparation, to John Sebastian Miller, of Pennsylvania.

9. A Case of Instruments, for the best original research in the Chemical Laboratory, to Charles H. Ballentine, of Pennsylvania: with honorable mention of the Essays of Horace B. Scott, of Connecticut; and Justin D. Lisle, of Ohio.

10. A Case of Instruments, for the best original research in the Materia Medica Laboratory, to Charles A. Koder, of Pennsylvania; with honorable mention of the researches of A. Rusling Rainear, of Pennsylvania; Jason H. Moore, of Kansas; Isaac E. Clark, of Texas; and Charles A. Service, of Pennsylvania.

11. A Case of Instruments, for the best Essay on a subject pertaining to Physiology, to Charles Z. Weber, of Pennsylvania.

It was announced that at an examination held in June, 1881, diplomas were awarded to John Fruit, Reid C. Matthews, and Oliver P. Stoey, of Pennsylvania.

The valedictory was then delivered by Professor Henry C. Chapman, and after the rendering of another musical selection and the benediction, pronounced by Rev. Dr. Nicholson the audience dispersed.

Alumni Meeting.

The annual meeting of the Alumni Association of the Jefferson Medical College was held March

29th, in the hall of the college building. Professor Samuel D. Gross, president of the Association, called the meeting to order. Letters from members abroad, regretting their inability to be present were read, after which the report of the treasurer, Dr. Hatfield, showing the expenditures of the year, was read. The following officers were elected to serve during the ensuing year: President, Professor Samuel D. Gross; Vice-presidents, Drs. E. B. Gardette, Ellwood Wilson, A. Hewson and R. J. Levis; Treasurer, Dr. N. Hatfield; Recording Secretary, Dr. T. H Andrews; Corresponding Secretary, Dr. R. J. Dunglison.

Alumni Supper.

On Tuesday night, March 28th, the supper of the Alumni Association of the Jefferson Medical College was given at the Hotel Bellevue, at which a large number of professors and alumni were present.

Professor Gross.

Professor Gross has resigned the chair of Surgery in the Jefferson Medical College, of which he has been the incumbent for twenty-six years. His son, Dr. S. W. Gross, has been elected to the chair of Principles of Surgery and Clinical Surgery, and Dr. John H. Brinton to the chair of Practice of Surgery and Clinical Surgery.

Physicians.

The following is the table of graduates of the medical colleges this year, as compared with those of last year:—

Essays upon The Radical Cure of Cancer, Offered for Prizes.

The undersigned, who, in October last, was delegated to receive competing essays on the subject of the radical cure of malignant disease, announces that three essays were presented. In the consideration of their merits the assistance of Dr. George B. Shattuck, editor of the *Boston Medical and Surgical Journal*, was invoked; and it has been decided that no essay is worthy of a prize.

The same subject, namely, "The Probability of the Discovery of a Cure of Malignant Disease, and the Line of Study or Experimentation likely to bring such a Cure to Light," is proposed for essays to be presented in competition, not later than the first day of December, eighteen hundred and eighty-three (1883), to the undersigned, who, with such assistance as he may select, will be the judge of their merits.

For the best essay on the above subject, a prize of one thousand dollars will be given, the right being reserved to withhold the prize in case no essay of sufficient merit be presented.

The sum above mentioned has already been deposited in the New England Trust Company, of Boston, subject to the call of the judges.

The essays must be legibly written in English, and neatly bound. Each one must bear a motto, and be accompanied by a sealed envelope bearing the same motto, and inclosing the name and address of the writer. They will all remain in the possession of the donor of the prize, for convenience of reference, and the privilege is claimed to publish the successful one, with the name of the writer. No writer, however, surrenders the privilege of retaining a copy of his essay, and publishing it.

The decision concerning the merits of the essays will be made chiefly from a practical standpoint, it being the object of the donor of the prize to obtain suggestions by which a search for a cure for cancer may be instituted.

For the donor,

J. Collins Warren, M.D.,
58 Beacon street, Boston, Mass., U. S. A.

QUERIES AND REPLIES.

S., Ky.—We know of only on which occurred in this city, and it was not positively proven to be due to the anæsthetic.

A. G. C.—Pure vaccine lymph is not a *poison*, in the ordinary acceptation of the term. It is absorbed by the lymphatics. It is not corruption in the true sense of the word.

Subscriber.—Continuance of the treatment you mention ought not, on general principles, to be at all injuricus, but with so powerful a drug, the patient ought to be carefully watched.

MARRIAGES.

HAYNES—FELLOWS.—On March 14th, 1882, by Rev. H. L. Jones, at the residence of the bride's parents, John R. Haynes, M.D., of Philadelphia, and Miss Dora Fellows, of Wilkesbarre, Pennsylvania.

MARKOE—SHELTON.—In New York, on Thursday, March 9th, by the Rev. Charles H. Parkhurst, D.D., Dr. Francis Hartman Markoe and Madeline, daughter of Theodore B. Shelton.

PATTERSON—BELL.—At Glendale O., March 8th, 1882, by Rev. Dr. Potter, at the residence of the bride, Dr. John E. Patterson and Mrs. Sarah E. Bell, all of Glendale.

DEATHS.

CHAMPLIN.—Dr. James T. Champlin, ex-President of the Colby University, died on March 15th, at Portland, Maine, of paralysis, at the age of 70 years and 9 months.

McFADDEN.—In this city, on March 12th, Dr. James McFadden, in the forty-ninth year of his age.

MORROGH.—At New Brunswick, New Jersey, Clifford T. Morrogh, M.D., on Monday, March 13th.

REESE.—At Knoxville, Tioga Co., Pennsylvania, on Sunday, December 4th, 1881, of typhoid fever, Alice M., wife of C. A. Reese, M.D., aged 34 years and 3 months.

SMITH.—On March 10th, Dr. George Smith, of Delaware County, aged seventy-eight years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

THE DISORDERS OF PRIMARY DENTITION.

BY. M. BLACHEZ,

Physician to the Hôpital des Enfants Malades.

Gentlemen:—There is no fact more generally recognized in infantile medicine than the influence exercised by dentition on the general health of children. "A fine child, until it commenced to cut its teeth," is not alone a familiar saying; the experience of the greatest physicians have proven its truthfulness. In all the best works on infantile pathology, both ancient and modern, the influence of dentition is regarded as indisputable. But it must be admitted that this doctrine has been, perhaps, carried too far; the best clinical observers have been obliged to protest against the assertions of many who would attribute most of the diseases from which children suffer to the influence of dentition. This protest is evident in the works of Rilliet and Barthez, in the clinical lectures of Trousseau, the treatise by Bouchut, and in Dr. West's remarkably practical book. None of these practitioners desire to exaggerate the rôle of dentition in the etiology of infantile diseases; but its influence in this respect is not contested or denied. It is, in fact, an opinion current in medicine since the days of Hippocrates, and confirmed by Sydenham, Haller, Hunter, and the cotemporary authors we have already cited. However, certain voices have been lifted against this generally received opinion. After showing that dentition has been accused of producing many disorders not referable to it, which is perfectly true, certain authors have denied that teething has any influence in the production of morbid phenomena.

M. Magitot, whose authority on any subject connected with the teeth cannot be denied, has particularly combated the commonly received opinion. In his work on the disorders attending the irruption of the teeth, published in the *Archives de Médecine*, in 1881, he seeks to prove that dentition has no part in the production of the disorders imputed to it, and that these disorders are merely coincidences. He recalls the opinions of Rosen, Andral and Trousseau, that great caution should be used regarding the disorders of dentition, an opinion carried much further in the works of the distinguished English dentist, Dr. Tomes. We will consider, later on, the arguments brought forward by M. Magitot to sustain his opinions. To commence with, it seems to me useful to consider the question under three principal heads:—

1st. Should we admit, in certain cases, the existence of a difficult, laborious dentition, and if so, what are the characteristic signs?

2d. Can this difficult dentition induce disorders proper to this condition, and characterized by their nature, course and duration?

3d. When a child is teething should all the maladies which may present themselves be laid to the influence of this physiological act?

These different questions do not appear to me of difficult solution. Dentition is a physiological act, but not necessarily accomplished, on that account, without pathological reaction.

Children who pass through the period of primary dentition without presenting any symptoms of suffering constitute veritable exceptions.

The incisors and the first molars often pierce the gums without provoking any very marked reaction, but the irruption of the second molars, and particularly of the canine teeth, generally causes much more trouble. The phenomena which accompany the eruption of the teeth have, with reason, been divided into local and general. The most common local phenomenon is salivation, and this is the more remarkable as the buccal mucous membrane in young infants is generally dry, as Dr. West has rightly observed. At the moment when the gums become swollen and the crown of the tooth becomes prominent through the thinned surface of the gum, then the infant constantly drivels, and wets several handkerchiefs in a few hours, which does not happen with a child before the fifth month. This exaggerated secretion of saliva can only be explained by the excitation transmitted to the salivary glands along the mucous membrane of their ducts.

If the irritation is more marked, and the child very impressionable, the hands are carried incessantly to the mouth, and the infant bites at and rubs against the gums any hard object within reach, particularly objects which communicate a sensation of cold. At a more advanced stage of irritation aphthae are developed and thrush may supervene. The gravest manifestations of the irritation produced by dentition constitute what has been called odontitis infantum, characterized by a veritable stomatitis with ulcerations, which may persist so long, and determine so much suffering as to give rise to great anxiety for the life of the child, although West has never observed any case where these disorders actually caused death. In the presence of such symptoms it is difficult to deny the possibility of local disorders induced by dentition. We admit that these grave symptoms are rarely observed, but Trousseau, Guersant, West, Rilliet and Barthez mention them, and their occurrence cannot be placed in doubt. It is not, however, on this point that the principal objections have been formulated; but against the disorders affecting the general system and imputed to dentition. It is, in effect, impossible to deny, with any appearance of reason, the existence and etiology of the local disorders, with which every physician is acquainted; but when we are in presence of disorders such as diarrhœa, skin eruptions, convulsions, fever, etc., which present nothing special, then it is less difficult to deny the influence of dentition, and pretend that the occurrence of these symptoms at this period is a mere coincidence; that these may be observed at any period of infancy, and that they are attributed, without any sufficient proof, to the effect on the general system of the process of teething. Nevertheless, no physician who comes frequently in contact with sick children hesitates in recognizing these evidences of constitutional disturbance as due, or referable to dentition, not in all cases, but in certain conditions of daily observation.

Reflex sympathetic phenomena are manifested in infancy with peculiar energy, of which we have daily proof; agitation, fever, vomiting and convulsions, are often induced by slight, but constant sources of irritation, such as a badly-placed pin or a boil irritated by the contact of dry and hardened dressings. How, then, can it be denied that a continuous pain in a swollen gum, which persists and cannot be relieved, may throw the infant into a condition often exceedingly distressing?

Since the application of a blister or sinapism often determines convulsions in a nervous child, why should the continuous irritation of dentition be incapable of producing the same symptoms?

It is true our opponents seek to establish that this pretended pain of dentition is purely mythical; that there is no reason why the eruption of the tooth should cause pain, since there is neither effraction nor traumatism, but a very gradual wearing away or absorption of the tissues of the gum. It would then be necessary to prove and demonstrate that the different tissues pushed outward and compressed during the evolution of the tooth do not suffer in any way from this compression, which it would appear exceedingly difficult to admit.

When a vigorous child of from six to eight months, nursed by a healthy mother with excellent milk, is suddenly observed to lose sleep and gaiety, become irritable and quit the breast after a few attempts to nurse, while at the same time it drivels incessantly; when, again, after a careful examination of all the functions, no explanation can be found for this change, except that the gum is hot and painful when touched, it must necessarily be admitted that the process of dentition has caused these disorders. A few days pass, the general malaise persists, or is augmented in intensity; diarrhœa may come on without any change in the habitual diet of the child. No active treatment is instituted, and yet, all of a sudden, the morbid symptoms disappear, and examination of the gum shows that the irruption of the tooth is complete. Can the conclusion, then, be other than that we have already formulated?

This is not a case invented for the occasion, but

a fact of daily observation; with some children even the irruption of each tooth or group of teeth is attended by these morbid symptoms.

If these facts are not constantly observed, they are at least common, and it is certainly very rare to find a child who has not suffered more or less during the period of dentition. I have observed, for my part, a child who never had one of his first twenty teeth without suffering from one or several convulsions, and who has never presented any since the period of dentition.

What we have said of the fever, diarrhœa, and nervous disorders, can be repeated with equal justice for the multiform eruptions frequently observed in similar cases. There is nothing special to distinguish these eruptions, any more than the intestinal or nervous disorders, from those produced by other and widely different causes. They demonstrate, however, the existence of disorders in the functions of the various organs, and in the secretions, produced by dentition.

What especially characterizes these eruptions is the period of their appearance and the manner in which they follow "the evolution of the teeth, preceding and accompanying the irruption of a group of teeth and then disappearing.

If all the morbid symptoms observed during dentition cannot be ascribed to this physiological act, it is not the less true that these disorders, appearing only at this period, accompanying the irruption of the teeth and ceasing when this is accomplished, do not leave in doubt their veritable causation.

It may be admitted that dentition is not an isolated phenomenon: that it coincides with a period of peculiar activity in the development of the child, principally with the formation of the bones, the increase of the glandular system of the digestive apparatus, and that at this moment the nervous sensibility is at its highest pitch.

This is all true, but it is certain that dentition, particularly when painful, has a preponderating rôle in the causation of these morbid manifestations.

After denying that teething can be of itself painful, M. Magitot demonstrates that traumatisms practiced on young animals at the period of dentition, and affecting more or less deeply the gum or the tooth, do not determine anything comparable to the disorders attributed in children to the evolution of the teeth.

We are of opinion that there can be no analogy between the sections, punctures and tearing of the alveoli in these experiments, and the normal evolution of the tooth, which separates, forces out and slowly compresses the tissues. This last is a purely vital act, not in any manner reproduced in the traumatisms already mentioned, which induce widely different reactions.

In the same way the numerous diseases of the teeth, caries, ulcerations, etc., may often induce very severe pain without provoking any symptom resembling those observed during the period of the evolution of the teeth. The reactions are peculiar to this period and are analogous to those observed during the evolution of other organs.

The opinions of M. Magitot are reproduced in the able and conscientious thesis presented by M. Levèque to the Paris Faculty.

We have particularly considered the seven observations given by M. Levèque, and we find that several might be given as types of the disorders induced by dentition, and the interpretation of them given by the author is, to say the least, extremely far-fetched. But these objections do not mar the value of the work; it is possible that the author will persist in his ideas if he practices dentistry exclusively. But it would be entirely different if he is called upon to follow, in their maladies and indispositions, young infants, to have them under his care during their development, and be obliged to interpret their sufferings. He would then remark, with all clinical observers, that dentition exercises a very marked influence in the production of infantile disorders, and he would soon recognize how solidly the opinion he combats to-day is established.

Communications.

PUERPERAL ALBUMINURIA.

BY J. L. MILLIKIN, M.D.,
Of Carmichaels, Pa.

Albuminuria (or the disease of which it is a symptom) is probably the rarest as well as the most dangerous of all the diseases of pregnancy, and its almost inevitable termination, eclampsia, carries with it the most terror; excites within the physician the greatest responsibility, and the necessity of prompt and decisive action. The importance of the subject, demanding from every physician the expression of every thought which may add in the least to our knowledge of so grave a condition, is my only reason for presenting the following case:—

On January 5th, 1882, I was called to see Mrs. H., aged 18, primipara, on account of swelling of the limbs and other parts of the body. Upon examination I found œdema of the upper and

lower extremities, and intense œdema of the external genital organs. She was, however, still attending to some household duties, and suffering no inconvenience, except slight headache, an occasional attack of nausea, and a stinging sensation in the swollen parts. Bowels regular, and amount of secretion of urine normal.

Inquiring into the history of the case, I found she had always enjoyed excellent health prior to her pregnancy; never had had any symptoms of renal disease; and that the first time she had noticed the swelling of the limbs was about four weeks previous to my visit, being now in the eighth month of pregnancy, according to the best data she could give. Impressed with the importance of examining the urine, I requested Mr. H. to bring a specimen to my office, for examination, on the day following, when, as I had great reason to suspect, I found it loaded with albumen, by the tests with heat and by nitric acid. I informed Mr. H. of the gravity of the case, enjoined rest, gave directions for the diet, and attention to the condition of her bowels, prescribing iron, as recommended by Cazeaux, and a decoction of uva ursi and buchu leaves, to keep the kidneys acting.

There was nothing remarkable in the case, except a slight diminution in the swelling, until the evening of January 7th, when she had nausea, was restless, and slept but little during the night. Early in the morning of January 8th she complained of pain in the head, and of seeing "balls of fire," etc. About 4 A.M. Mr. H. came for me, in great haste, saying "come quick, Doctor, I'm afraid my wife is dying." I dressed as quickly as possible, jumped on his horse and galloped to his residence, a few steps out of town. Dr. J. A. Gilbert, of this town, was called simultaneously, and arrived a short time after I did. Finding my patient, on my arrival, in violent convulsions, I bled her freely from the arm, and by that means controlled the convulsion, restoring her to partial consciousness for a few minutes, during which time she exclaimed "I'm blind." There was soon, however, a complete suspension of the sensorial and intellectual faculties. A digital examination revealed no signs of approaching labor. Several convulsions succeeded the first one, which could only be controlled by chloroform, during the intervals of which she remained in a half conscious state, but showing no signs of intelligence. About five hours after the first convulsion there were some signs of labor,

Dr. A. Patton, of Jefferson, Pa., was called in consultation, and by the time of his arrival, noon, we were able to introduce the finger into the os uteri, and diagnosed a vertex presentation.

After consultation, it was decided to bring about delivery as soon as possible, as the only means of saving the life of the woman, and as offering the best chance for the life of the child.

Accordingly, I introduced my finger, and finding the os dilatable, ruptured the membranes, and gave ergot. She could swallow but little, and we gave it per rectum. Used the finger frequently, to assist in the dilatation of the os. The pains now came on more violently, during which there was at each time an exaggeration of the convulsive condition, which was controlled by chloroform. A large enema of warm water cleared the rectum of fecal matter, and also acted by sympathy in increasing the contractions of the uterus. At 8 P.M. we decided upon an attempt at an application of the forceps, although the descent of the head of the fœtus into the pelvis was scarcely perceptible, and the os dilated but little. Dr. Patton etherized the patient, and I applied the forceps and delivered the woman of a dead child, which was poorly developed, and evidently had been dead several hours. Had some difficulty in removing the placenta, which was adherent, having to dissect it from the walls of the uterus with my hand. After delivery there was a complete cessation of a tendency to convulsions, though she lay in a stupor. Used stimulating enemata, and she was soon able to swallow a little whisky and aromatic spirits of ammonia.

About this time a messenger came for me to attend a labor case six miles in the country, and there being indications of reaction, I left the case in the hands of Drs. Patton and Gilbert, while I would attend to the call and return.

I returned by 9 A.M. the next day. She was now able to take a little nourishment; the stimulants were continued, and by noon she could distinguish persons, and in a few hours consciousness had fully returned. From this time there was nothing unusual in the case; it progressed favorably under the influence of tonics and diuretics and stimulating regimen. A copious secretion of urine relieved all œdema, and in ten days from the time of delivery there was not a trace of albumen in the urine.

In conclusion, I desire to insist upon the importance of making frequent examinations of the urine of all pregnant females suffering from any disorder whatever, and especially when there is any tendency to œdema, so that an early diagnosis may be made and the proper treatment applied. As the main feature in the pathology of

the disease is an altered state of the blood, consisting chiefly in a diminution of its solid constituents, it is self-evident that the treatment should be reparatory. Unless there should be symptoms of renal congestion or general plethora, bleeding would be contra-indicated in a disease attended with so great impoverishment of the system. A stimulating diet, rest, ferruginous and vegetable tonics, should certainly form the basis of the treatment.

A REMARKABLE BRAIN WOUND.

BY R. R. PURYEAR, M.D.,
Of Wylliesburgh, Va.

In the issue of the MEDICAL AND SURGICAL REPORTER, of the 28th January last, I read with interest the report of a case of "A Penetrating Pistol Wound of the Brain," by Dr. J. Foster Bush. By this I was so forcibly reminded of one that came under my charge in 1879, that I have thought it well to give it publicity.

On the night of the 16th of January, 1879, I was called hurriedly to see J. Mc., an Irishman, aged 40 years. On arrival received the followiug history: The hour of retiring having arrived, Mr. L. (his room-mate) walked out to attend a call of nature; the night being cold and rainy, he lost no time in its dispatch, returning to the room with his pants in no particular condition, a pistol in his hip pocket. Seated himself hastily in a wood-bottom chair, while Mc. was stooping over in front of him, untying his shoes. The moment L. seated himself the pistol was discharged, and Mc. fell from his seat to the floor. The alarm created by the report of the pistol caused all in the house to rush to the room; finding Mc. as above stated, promptly put him to bed, where I found him. On examination found him unconscious, the general surface of the body and extremities cold, particularly the right side. On examining the head I found the ball had penetrated the cranium directly through the left parietal bone, equidistant from the coronal and sagittal suttures (say one inch) from which opening was oozing brain tissue mixed with blood; on the pillow was visible at least three ounces of brain tissue that had previously escaped. Hoping to find the ball near the surface, I used my little finger as a probe, which I cautiously introduced to its second joint; not touching the ball, I next resorted to the female catheter, using it likewise as a probe, which of its own weight descended three inches, no ball touched; I removed it and applied cloths wrung out of cold water to the wound and stimulating applications to the extremities. Pulse feeble all the time, ranging from 50 to 60 per minute during the night, associated with stertorous breathing.

On the following day the breathing was heavy; no change in the pulse; brain tissue still escaping; surface cold, particularly the right side. Liquids put into his mouth could be swallowed with great difficulty, always attended with a spasmodic cough. With the catheter his bladder was evacuated every six hours; no return of consciousness. On the third day, under the influence of stimulating enemas, his bowels were partially evacuated. Continued the use of the catheter, frictions and stimulating applications to the extremities; cold cloths saturated with carbolic water applied to wound. The brain tissue now ceased to come away. Liquid food continued; deglutition much improved. On the fourth day found his left side, leg and foot warm. The right side, leg and foot still cold; a sanious discharge from the wound; pulse 75; a partial return of sensation; would occasionally move his left arm and leg; right leg and foot responding to no impression made on them. Could now swallow with sufficient ease to enable me to administer an aperient. He now passes his water in bed. Showed signs of hunger. Cold cloths saturated with the carbolic acid water continued. On the fifth day pulse 80; could move his left arm and leg sufficiently to enable him to change his position in bed; right side perfectly paralyzed; could not speak, but with signs could show his approval or disapproval of services performed by attendants; had a copious action from his bowels; passed his water to-day in vessel, which was handed him in response to signs he gave.

From this date he steadily improved, to the eighteenth day, with no further attention bestowed than to keep his bowels, kidneys and skin up to their duty. On this day I was called to see him; on arrival learned that he had been suffering for the past eighteen hours with a throbbing headache and general fever, and a few hours previous had a couple of "fits." Finding the secretions generally well kept up, I next looked to the wound, which had entirely healed and puffed up above the surface of the scalp; to the touch fluctuation was apparent; on simply cutting through the skin the pent-up matter made its exit, and with it the headache and "fits. On the following day found his articulation so much improved that he could make himself understood by all bystanders, and could use his right arm and leg well enough to enable him to go about

the room when he wished. Two months from this date he was in active employment, having nothing to complain of save a dull aching in the right shoulder whenever he walked any distance, or used the axe or hoe "right-handed" (by this he meant right hand foremost on the helve). These latter troubles continue to this day.

But, not to anticipate: In the latter part of the year 1879 he left this location and went to Claremont, the location of a second colony in Surry county, this State; there he contracted chills and fever, which continued on him to a greater or less extent till he returned to Barnesville, in October, 1881, a perfect wreck in appearance and health; he then came under my treatment again; after relieving the chills and restoring the secretions I thought him well, but to my surprise, at an early day I was called on to treat him for "fits," as they were called. On my arrival my attention was at once directed to this old wound (no hair on his head to obstruct view), the skin over which was much elevated and fluctuation unmistakable; on reopening this wound, the matter again escaping, relieved him at once. On interrogation, he informed me that he had had two similar attacks during his stay at Claremont, and in neither case was he relieved till the old wound reopened itself by suppuration.

In the history of this case a few interesting points present themselves for solution:—

1st. Where did this ball make its first lodgment?

2d. Paralysis (the effect) having ceased, must not the ball have changed its location? Or, have these decussating nerves the ability to harmonize the presence of this foreign body with the performance of their natural functions?

3d. By books we are told that leaden missiles soon become encysted, and as a result, cease to irritate; then why these frequent suppurations for the past three years?

4th. If not the ball, must there not be some foreign body or substance, an irritant present in the brain, that the vis medicatrix naturæ is attempting to throw off by suppuration? If a foreign body or substance, can it be spiculæ of bone?

5. Why these abnormal pains in the right shoulder and arm after the special use or labor mentioned?

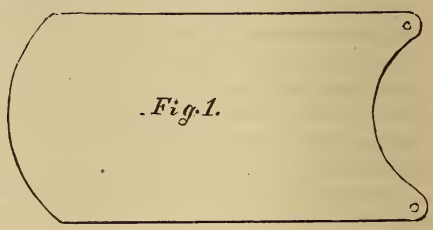
—Dr. Charles M. Seltzer, 1530 Fairmount Av., has been elected Treasurer of the Alumni Society, Univ. of Pa. *vice* Dr. T. H. Cathcart, deceased.

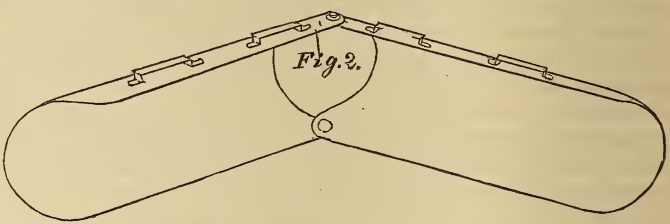
SPLINT FOR FRACTURE OF ELBOW.

BY N. S. READ, M.D.,
Of Chandlerville, Ill.

In the treatment of injuries of the elbow-joint, in order to give the patient the best possible chance for a perfect recovery, it is necessary, in many cases, to keep up passive motion, and in some cases to make light pressure on the condyles of the humerus. I have contrived a very simple appliance, which I exhibited at the last session of the Illinois State Medical Association.

It consists of two pieces of tin, represented in Figure 1. The splint, when completed, is shown in Figure 2.





It answers every indication of either Welch's or Bond's Splint, and, in some respects, I think it superior.

The tins should be cut in length to correspond with the length of the arm and forearm respectively, and the width equal to about two-thirds the circumference of the arm. There should be four staples made of tin, folded on itself, in order that the edges may be smooth, and soldered near the edges of the strips of tin, through which tape can be passed, to confine the splint to the arm. Two copper rivets and washers, such as can be found at any hardware store, and the materials for the splint are complete. The two pieces are next curved to fit the arm, and the rivets passed through the holes, from within outward, and riveted over the washers, forming a good strong joint.

The advantages of this splint over any other that I know of, are, First, its cheapness and the ease with which it can be constructed. Second. The tin can be formed to fit the inequalities of the arm. Third. As much or as little pressure

can be applied to the condyles as desired. Fourth. The arm can be dressed at any angle required, and if desired fixed there by attaching a wire to one of the staples of the arm and forearm of the splint. Fifth. Any amount of passive motion desired can be kept up by the patient without danger of displacing the fracture, which is of the greatest importance in treating injuries of the joint.

VENESECTION IN PNEUMONIA.

BY E. O. BARDWELL, M.D.,
Of Emporium, Pa.

Although much has been said on this subject recently, it occurs to me that there is still opportunity for more. In speaking of blood letting it should be remembered that venesection was brought into desuetude by its indiscriminate and irrational use; and much as it is to be deplored, it is nevertheless true that mankind in general show a remarkable tendency to rush blindly from one extreme to another. Writers supporting a particular line of treatment are prone to become excited, and to come very close to calling their opponents fools. This is not argument, and is not at all conducive to an impartial consideration of their statements. Put forth with so much spirit the wind of oratory sweeps away the truth that is in it. There are physicians who would not bleed under any circumstances; there are others who would not apparently like to see venesection practiced as it was forty years ago. It is my opinion that the greatest good to the greatest number will be favored by a healthy conservatism.

It is impossible that a plan of treatment followed to the extent that phlebotomy has been should not contain something beneficial; it is just as certainly impossible that it could have been so completely dropped unless it also contained seeds of error; as the subject of venesection is being revived, let us study the indications for its practice, rationally, dispassionately, and without prejudice, if that is possible. Pneumonia, at present the disease illustrative of the curative and ameliorating powers of venesection, requires other agents besides bleeding, for its proper treatment. Seen in the outset, tr. aconite rad., given in one-half drop doses every fifteen minutes for two hours, followed by one drop doses every two hours for twenty-four hours, will often abort an attack of pneumonia; it is not always necessary to wait so long before using other measures; if no amelioration is apparent in six hours the abstraction of blood, either local or general, is indicated, and will be all the more beneficial in its results from the prior administration of the arterial sedative and diaphoretic.

After twenty-four hours, as a rule, the indications for the use of aconite are past, and carbonate of ammonia, combined with either quinia in small doses, or with morphia, or with both, as may be indicated, will be followed by good results.

The exhibition of the above therapeutic agents will not be contraindicated by prior venesection, and their value may be much enhanced in the later stages by the application of cups, wet or dry, according to circumstances. Treatment will not be satisfactory if forcing nourishment into the patient is practiced during the early stages, nor will it prove so if proper pabulum withheld during the later stages.

Moderation and independence, if conjoined with common sense, will work better in the majority of cases, than following blindly the dictates of any leader.

HOSPITAL REPORTS.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINIC OF ABRAHAM JACOBI, M.D.

Nævus.

GENTLEMEN:—This little baby, seven weeks old, has, as you see, an elevation of the cutaneous surface at the outer angle of the right eye; it is about the size of your little finger nail, red in appearance, and has a feeling as if extending down into the subcutaneous tissue. It has been present ever since the birth of the child, and of late has increased in size more rapidly than at first. There is danger, therefore, that if it be left alone it may extend to the eyelids and conjunctiva. The name of the tumor is nævus. We will remove it with the actual cautery, not heated to a white heat. You observe there is some bleeding from the superficial vessels, but that will cease of itself. It is better to perform a second operation than to carry the first one too far, and should it prove that we have not removed it entirely the mother will bring the child back again within two weeks and the cautery will be applied again.

Peri-bronchitis.

On examining this boy, aged about eight years, you will observe that his chest is constricted above, flattened both before and behind; that below there is a drawing in, as it were; and that it is flattened on both sides. The veins of the chest are rather conspicuous. Without asking any questions with regard to the boy's history, we would infer, from these facts, that there is some obstruction to the circulation, and we would expect to find it either in the lungs or in the heart. On examining the heart we can hear no murmur, and there is, therefore, probably no mitral lesion which would account for this congestion of the

veins. We may suppose, then, that the trouble with the circulation lies in the lungs.

The full, expanded form of the chest which characterizes it in health is almost entirely changed, being flattened from before behind, and from side to side; therefore, whether the process in the lungs has preceded or followed this change in the configuration of the chest, it must, at any rate, be of old standing; if there be pulmonary disease it must be an old one. A recent pleurisy or pneumonia would not give rise to such deformity of the chest and dilatation of the blood vessels. The two conditions of the lungs which may give rise to such an appearance are chronic bronchitis, with or without emphysema, and phthisis. Cases of phthisis do occur in children as young as this boy, but as a rule in this disease, whether in the child or adult, the deformity is mostly on one side, whereas here it is about symmetrical. If the case be one of bronchitis, you may call it, as you please, a case of chronic pneumonia or a chronic bronchitis; the meaning is that there is a hyperplastic inflammation of the interstitial tissue around the bronchi, rather than inflammation of the mucous membrane of the bronchi. If one speaks of a bronchitis he means inflammation of the mucous membrane of the bronchi; if he speaks of a peri-bronchitis he means inflammation of the interstitial tissue between the smaller and around the larger bronchi, with thickening of the bronchi, having the effect of compressing, narrowing their size, but now and then, however, producing dilatation If you will imagine that around a larger bronchus there is a good deal of exudation, of hyperplastic tissue proliferation; that after a while induration takes place in this; the tissue, instead of remaining heavy, thick and voluminous, contracts, or, as it were, cicatrizes, as in the case of a scar; you will see that the wall of the bronchus is pulled upon on every side outwardly, and what has been called bronchiectasis is produced. Not infrequently the diagnosis of phthisis has been made in cases which were simply illustrations of dilatation of bronchus in consequence of peri-bronchitis.

On the right side, here, I find an unusual amount of so-called puerile respiration, a harsher, coarser respiration than we find in the normal lung of an adult. The expiration on the right side is more prolonged than inspiration, as compared with the left side, and it is evident that more peri-bronchitis has been going on in former times on the right side than on the left.

If there were emphysema in this case, the thoracic walls would probably bulge out more than they do. There would be a large thoracic cavity with comparatively little respiration going on, and instead of finding a certain degree of dullness, there would be a sonorous, respiratory percussion sound, which would extend over the heart region, reducing its area of dullness to a considerable extent. Such, however, is not the case here. The area of dullness over the heart is, on the contrary, enlarged.

To what cause shall we attribute the enlargement of the heart in this case, since there is no murmur? The enlargement is particularly toward the right. "To an over-worked heart." Yes; the heart has been compelled to labor against an obstruction in the lung, of years' standing, the obstruction being due to peri-bronchitis many times repeated, and resulting in chronic induration.

He has a temperature at present of 102° F., which would indicate that there is a process, either of a general or local character, going on, and producing fever. There is a mucous râle heard over the left side, and it is probable that he has a recent catarrh, which will probably pass by, though he is more imperiled by such processes than most children of his age. By having him go to bed now, and giving him some quinine, I think another bronchitis and peri-bronchitis may be warded off.

What would be the general indications for treatment? "The best possible nutrition." Yes, that is true, but there has been a process going on in the lungs which calls for attention. If it can be fulfilled, the indications in my mind would be, to reduce the amount of exudation in the lungs; to do away with those parts which are still being dissolved; and there is one remedy which in a number of cases does a great deal of good, viz., iodide of potassium. This drug will have the effect of dissolving, absorbing, aiding in eliminating material that is not absolutely permanent. When the exudative material has become absolutely firm, undergone a change into connective tissue, the inference must be that in the majority of cases the iodide of potassium can be of no use. But there are exceptions to this rule. Such exceptions are, for instance, in the formation of connective tissue of a syphilitic origin; we know these are exceptions; and it appears there are some other exceptions also, for we know, both experimentally and empirically, that a great many cases of asthma dependent upon emphysema and peri-bronchitis are very much improved by the internal use of the iodide of potassium. It appears to me that there is no other explanation for this fact than that the iodide does absorb, does dissolve, this material. I should, therefore, judge that it was unnecessary to wait until this boy develops more emphysema and has attacks of asthma before giving him the drug, but begin its use at once.

On the other hand, and this is a matter of some practical importance, we shall have to watch, and see that the iodide of potassium does not disarrange his stomach. We ought also not to lose sight of the fact that the iodide of potassium is able to dissolve and to absorb that which we do not want it to dissolve and absorb; but it is true, again, that when a given remedy is clearly indicated to produce a local result its action will be directed to that object, whereas under other circumstances it might affect other parts. Or, this boy might be given, if you prefer, the iodide of sodium. I should not hesitate, however, to give him four or five grains of the iodide of potassium, three times a day, in plenty of water, some little time after his meals, not beginning its use until his fever has ceased. At present, I would put him to bed three or four days; give him a dose of eight grains of quinine about eleven o'clock every day, and a dose of opium, say five grains of Dover's powder, every night, if he coughs much, and keep him on warm drinks, and let him perspire a little.

Now, these are cases which we meet with in ordinary practice, and it is important to understand them, and treat them aright, for if this boy does not get well now, he never will; he will be an invalid all his lifetime if he is allowed to grow up in this condition. You can readily see of what vast importance an early diagnosis is in such cases, in the very commonest family practice.

CLINIC BY PROF. ALONZO CLARK, M.D.

Bright's Disease.

This patient, a man about thirty-five years of age, complains of a cough which has lasted six months, and of a smothering sensation of six weeks' duration. In reply to my questions he states that he gets out of breath on going up stairs, that he never had rheumatism, that since about two months he has had swelling of the stomach and legs, also some swelling of the face; and he has not felt well generally. His business is doing general work about a sugar refinery, lifting machinery, etc. There is, therefore, nothing about his employment which would suggest the possibility of anything acting upon him chemically to produce ill health. He says his urine is the same as usual in amount and color.

His referring the sense of oppression to the cardiac region suggests the propriety of examining for heart disease. His urine has just been examined for albumen, by boiling, and is found to contain it in moderate amount. Adding a drop of nitric acid to this, it does not clear up, which shows that the deposit is not of phosphates. Alkaline urine should be rendered acid before a thorough test for albumen can be made by boiling; the color, which is light, evidently indicates low specific gravity.

Examination shows no abnormal prominence over the region of the heart; the beats are very much like those of the town clock—regular; no murmur can be heard; the heart is not enlarged; there seems to be nothing about the heart, therefore, to account for his sense of suffocation, which is present under certain circumstances. Possibly there is an effusion into the pleural cavity, which may account for the oppression of breathing. On inspection you will observe that on the right side, behind, there seems to be some bulging of the chest walls. The voice-sound is more distinct down to about two fingers' widths below the angle of the scapula on that side, than it is below that point, and percussion dullness begins at about the same place. It is very likely the breathing sounds will be heard less distinctly below that point, perhaps not audible at all. I find it not to be so, however; it can be heard all the way down, and it is probably due to the sound being conducted by the walls of the chest. We find about the same signs on the left side. Percussion resonance is changed with change of position of the patient. There is evidence of more fluid on the left side than on the right. Here, then, we have an explanation of the sense of oppression which he experiences on going up-stairs.

When there is albumen in the urine, and the urea circulates in the blood more than it should, it is not an uncommon thing to have a pleuritic effusion; and when it occurs from this cause it is almost always double. It is much more apt to occur where there is regurgitation at the mitral valve. In this instance the heart seems to be sound, and this case shows, therefore, that passive pleuritic effusion may occur where there is no regurgitation of blood. The reason why it is much more apt to occur when there is a valvular murmur present, is, that the blood is set back upon the lung and congests the vessels belonging to that system, and thus induces an effusion of the fluid there.

The case, then, is pretty well before you; it appears to be one of simple Bright's disease, and not very far advanced. There is not much swelling of his legs now; there has been more. By proper treatment he will probably be able to get rid of his effusions in large measure, or completely, and then he will be much more comfortable.

It is important for him to be in an atmosphere of even temperature, and not expose himself to the cold; and, being a poor man, it is probable he cannot have these advantages at his home, and a residence in the hospital, where the temperature is kept uniform, would do him good. The effect of exposure to cold in these cases, even when the person is not conscious of being cold, was illustrated in a case I have under care now. A gentleman who had had this double pleuritic effusion, and this swelling of the legs, had become almost entirely relieved of it, and, without my permission or knowledge, he took a drive one pleasant wintry day; but it was too cold. The next day fluid reappeared in the chest, to a point higher than in this case, and all in the period of one day. Another instance can be cited, illustrating the same thing. Some years ago a ward in which the servants slept, at the hospital, was used for minor purposes, and at this time I had charge of it, there being five or six cases of Bright's disease in the ward. One November afternoon a carpenter, after I had been there, opened a large hole in the floor, and the cellar doors were opened. It happened to be rather a cold night for November, and all of these poor people, those who had Bright's disease, as well as the rest, were exposed to the chilling of the night. The house physician did not know it, and had no opportunity of giving them additional clothes. The result was that every one of them was worse, and one or two of them were so much worse that they died in a few days.

I would advise this man, therefore, the first thing, to confine himself to the house, and if he cannot live without earning something, go to a hospital of his own selection, for there are enough of them in New York, and be treated there. Besides confining himself in a house of an even temperature, he should take diuretics; the acetate of potash, perhaps, will suit him better than others. It is less expensive than the effervescing mixture, the lemon juice and potash, which I have before spoken about, and is about as good as a diuretic. I prefer the lemon juice and potash, because it almost always agrees with the stomach, and that is not true of the acetate of potash; the latter is often vomited. The acetate of potash, taken in about twenty-grain doses every two hours, and a dessertspoonful of the infusion of digitalis three times a day, will very likely increase the action of his kidneys, and relieve him of this effusion. As to the kidney

trouble, which seems to be rather recent, dry cups in the early stage, over the loins, should be applied; and the india-rubber top cups are best, because they can be applied frequently. They do not draw so firmly as to make the parts sore, and they are also better in another respect, that any member of the family can put them on. They may be applied three, four, or five times a day, and thus may be of great advantage.

Renal Calculus.

This young man says he suffers from stones in the kidney, and describes his symptoms as pain in the left side and back, and top of the hip, passing from the back, over the hip, toward the front, on the left side. He first felt the pain a year ago last summer, and it returned last spring. It is of a sharp, jumping character, like the toothache. He cannot lie still when it comes on, but tosses about. That is an important point. I have in my mind now a lady who is suffering from this trouble, and the almost diagnostic fact was that she would lie with her head at one end of the bed this minute, the next minute it would be at the foot of the bed, then she would be out on the floor, then on the sofa, tossing about the whole time. Neuralgic pain does not impel a person to that kind of restlessness.

He says the pain comes on sometimes every other day, sometimes every three or four days, but he says it does not increase the pain to walk. This is a point of considerable importance in the diagnosis of imprisoned calculus. Walking brings into action the psoas muscles, the belly of the psoas pushes against the ureter and excites pain. I have known several cases of imprisoned calculus in which this was a very valuable aid in the diagnosis. The patient, after walking twenty rods or more, has a pain which induces him to stop, and after a little he can walk on again. After getting home and lying down, the pain disappears in about twenty minutes. I am not sure that a calculus in the pelvis of the kidney would be acted upon in exactly the same way, but if it is imprisoned in the ureter that symptom is a great help in the diagnosis.

This patient says his urine has been examined by a physician, who did not say that he found anything wrong with it. He has never seen any blood in it. In some cases of imprisoned calculus the urine is bloody at times. He says the pain is sometimes very severe in the left testicle. He has not noticed that that testicle is drawn up into the body. When present, retraction of the testicle is also another very useful guide in the diagnosis. His urine continues to flow in a full stream until the bladder is empty; has no pain in the penis, except a little at the head, sometimes, after urination. He vomits, principally in the morning, and a great deal when he has pain; and it seems to relieve the pain at times. One of the Chancellors of New York used to say that, if the books were to be relied on, he had been pregnant for seven years; he had morning vomiting for that period of time.

We now get a point which seemed not to be present in this case, according to the patient's statement a moment ago, namely, that jarring in a wagon seems to bring on this pain; it then continues, perhaps two hours, when quiet relieves it, and it is brought on again by moving about. But it sometimes comes on when he is lying still.

It would be a further aid in the diagnosis if his urine were examined to determine what may be the character of the sediment, or turbid state, of which he speaks; whether it contains uric acid, or whatever it may be. The diathesis is an aid to the diagnosis, and that is best illustrated by a microscopical examination of the urine.

I think it is safe to say that he has a calculus, either at the opening of the left ureter, or in the pelvis of the kidney near the opening of the ureter, and that that causes his pain.

Next, how can we relieve him? I do not know of anything for him to take but faith in the future. A physician, at one time a resident of New York, but at the time he came to me he lived a hundred miles away, presented symptoms very much like those that we find in this patient, and I made the above diagnosis, and told him that the only chance for him was that the offender would come down in the end, and pass off from the body. He waited for one year, and then another, coming to me once in a while to relate symptoms. Still another year passed by, and he went pretty well into the fourth, when he had an attack of pain that was more severe than any he had before, and he had then a consciousness of relief at the point where the suffering had been greatest. He then waited for the further discharge of it, and was in a country privy, under which was a pit, when he felt the enemy approaching; he was conscious of its entering the urethra, and he put his hand down to catch it as the water was flowing, but he was not quite quick enough. He heard it thump against the upright of the seat, and fall away into the pit, and it was lost to him, but ever after that he was relieved of pain. I have known one or two other instances of that kind.

There is nothing that will dissolve the stone in its position, and it is out of the reach of surgery, unless in these daring days of surgical operations somebody were to conceive the idea of cutting in from behind, entering the ureter and taking the stone out. Such a thing would not be bolder than a great many things that have been done.

There is another mode in which this irritant sometimes behaves. A physician in this city, about thirty years ago, had pains of this sort, that tormented him for two or three years, and he, at length, was laid up by a steady pain in his back; he was conscious that something new was there, and he sent for Dr. Wood (his case being a surgical one); Dr. Wood cut into the muscles of the back, a distance of about an inch and a half, and let out a large quantity of pus, and with the pus came a calculus. It was as large as the end of my thumb, and, of course, it was impossible that it should have passed by the ureter unless that were greatly enlarged. After the discharge of this pus, and the disappearance of the illness that was consequent on the formation of an abscess, he was up and about, and attended to his business, visiting his patients. A year or two after that the same accident occurred again, and to make a long story a short one, he presented to me the seventh calculus that was removed in that way by an abscess, generally opened by the surgeon, in the back. The space

all about there, doubtless, had become adherent by the inflammatory action, so that there was no danger of the pus getting into the peritoneal cavity. He did not die of this trouble. He lived twenty years, probably more, after the first calculus was removed in this manner, and finally died of consumption, possibly induced by the weakening influence of these repeated abscesses; but that is the only way in which he could have been said to have died of the calculus.

The appearance of the back in this case is normal. He complains of a cough; but fresh air will do that most good. The question of prescription I think is answered in general by the indications of his countenance. Observe, he is rather thin, and has not quite a healthy look. I should say he needs tonics; and probably vegetable tonics would be of more service than the mineral. He might take some chalybeate, and the easiest of all of the iron medicines to take is that which I have spoken of before, the chocolate lozenges, containing two and a half grains of the proto-carbonate of iron each. Another point is yet to be decided by a further examination of his urine. We do not yet know whether it is disposed to alkalinity or not. If it is, then the sodas and alkalies would hardly be suitable. If it is decidely acid, then the bicarbonate of soda would be of service, and a person in his condition should take it by test. The urine should be tested in the evening, with litmus paper, and it should never be allowed to come to full alkalinity. The urine will not deposit any phosphatic matter upon a calculus if there be a slight appearance of redness on the litmus paper which is used in testing it. I say not to test it in the morning, because a healthy man's urine is sometimes alkaline in the morning. He should never take enough of the alkali to leave the urine in an alkaline condition at night. As I said before, the great medicine for him is hope in the future.

Bronchitis.

This young man complains of a cough, of four or five months' duration. He has had it during the winter, as far back as he can remember, but heretofore it lasted only a short time. Before making an examination of the chest, we should infer, from his appearance and his statement, that it is altogether likely his cough is due to a common catarrh. But I knew a gentleman who would have the symptoms of consumption coming on as winter occurred, beginning usually in December. He would cough, and raise a good deal; would raise blood in coughing, would have night sweats, and grew thin. That would continue until June or the latter part of May, and then the cough would cease, and after a few days he would get strong enough to get into his buggy and ride out to see his patients, and this occurred marvelously, thirty-five years in succession. He had consumption every winter and got over it in the summer. I have not heard anything of him for nearly thirty years. A friend from his city came to consult me lately, and promised to get the man's further history and send it to me, but he has not yet done so.

The sweating which this patient says he has had on single nights at times is probably due to an extra amount of clothing. I find, on physical examination, only signs of bronchitis. The best prescription for him would be three ounces of the syrup of senega and half an ounce of paregoric, a teaspoonful every four hours. Also friction of the chest in the morning.

Editorial Department.

Periscope.

Locked Twins.

Dr. J. Arondel Barton reports the following instructive case in the *Lancet*:—

On the morning of the 18th of August I was sent for to attend Mrs. C., who was reported to be then "strong" in labor. On my arrival I found the patient to be a robust young woman, very short in stature, and eighteen years of age, and in her first labor. The nurse informed me that she had been in labor for over twelve hours, and that she had not expected to be confined until the end of October. On examination I found the vagina well dilated, the membranes ruptured, and the breech of a fœtus presenting well down in the pelvic cavity. The pains being very irregular and feeble I administered a subcutaneous injection of ergotine, shortly after which the pains became regular and strong, and the breech and body of the fœtus up to the level of the umbilicus were expelled. No further progress being made, I, after a short delay, passed my forefinger up over the thorax of the fœtus to the neck, in the cavity of which I found a round mass, which I at once recognized as the head of a second fœtus, the chin of which was firmly locked with that of the presenting fœtus. I endeavored by all the means that occurred to me to dislodge the two heads, but all my efforts were fruitless. At first sight it appeared to me that there was no way out of the difficulty except decapitation of the first or perforation of the head of the second fœtus; but, on further consideration of the fact that the age of the fœtuses was at most six and a half months, and that, consequently, they were of small size and easily compressible, and further, that the pubic arch was very wide and the vagina well dilated, I determined to attempt to pass up the blades of the long forceps over the surface of the first fœtus, and to fix them on the head of the second, and try to deliver it before the other. This I proceeded to do, first administering chloroform. After considerable difficulty I succeeded in passing both blades up over the body of the presenting fœtus, and getting them locked on the head of the second, and then in a short time I had the satisfaction of delivering first the head, followed shortly after by the body of what was

the second fœtus; the child was alive, and appeared to be somewhat over six months old. In a few minutes the other fœtus was also expelled, followed in due course by the placentæ. There was no rupture of the perineum, nor more than the usual quantity of hemorrhage. The mother recovered without bad symptoms. The children, of course, died within a few hours.

The case is chiefly interesting from the fact of labor coming on at a sufficiently early date to allow of delivery without decapitation or perforation, as, of course, had the case gone on for a very short period longer such operative procedure as I employed would have been quite out of the question.

Bilharzia Hæmatobia.

At a recent meeting of the Pathological Society of London (*Lancet*), Dr. Zancarol showed specimens of bilharzia hæmatobia, from patients dying in Alexandria. One patient was an Arab, who died with dysenteric symptoms. Vegetations were found in the large intestine, which showed bilharzia ova between the glandular and muscular coats. Another specimen was a section of hypertrophied bladder, with vegetations. The mucous membrane was thickened, and in its deeper parts was crowded with ova of bilharzia. The male adult worm of bilharzia was also shown. It was removed from the portal vein of a patient. It was about an inch long. The female is shorter and more slender. Dr. Zancarol stated that the parasites are only found in the portal, mesenteric, hæmorrhoidal and vesical veins. The ova in the urinary tract have a lateral spine; those in the intestine have a terminal spine. He suggested that the parasite, and particularly the ova in the urine, had some influence in the production of vesical calculi. Dr. Zancarol also showed a number of stones from patients in whose urine or bladders bilharzia hæmatobia had been found. Dr. N. Moore stated, that in a patient who acquired bilharzia three years ago, there have recently been found filariæ in the blood during the night. He asked if this had been observed before. These parasites, no doubt, enter the body by the mouth; but he had heard that, in Africa, the natives believe they enter by the urethra, and therefore tie its orifice when swimming. Mr. Bryant asked if there were any special symptoms of the condition of bladder caused by the parasite. Dr. Zancarol had never seen filariæ in natives with bilharzia; but once a friend of his found something very like filaria. The bilharzia exists in Arabs who drink the undistilled water of the Nile, and Europeans are only attacked when they have been found to drink the same water. The chief symptom of this form of cystitis is hæmaturia, and the diagnosis is made by the microscope. The best way to find the ovum in the urine is to try to get out some yellow and dirty specks, and in them the ova is sure to be found. The embryos cannot live more than twenty-four hours in the urine; they are like pumpkin skins, surrounded by ciliæ, and possessing active movements. Many patients infested with bilharzia live for years, even without serious suffering, only occasional cystitis and hæmaturia. The disease requires no special treatment; once in the body, it is impossible to destroy the parasite; but good hygienic treatment will secure immunity from suffering for years.

Irritating Subcutaneous Injections of Nitrate of Silver.

According to Paris *Médical*, these injections, recommended by Dr. Luton, have given excellent results in three cases treated by Dr. Arturo Mazzoti. The first case was that of a woman, 40 years old, suffering a long time from a very violent pain in the left sub-scapular region. All other remedies having failed, irritating injections were decided upon, and with the aid of a Pravaz syringe, 15 drops of a 30 per cent. solution of nitrate of silver were introduced under the skin.

Immediately after the patient experienced a sensation of great warmth, followed, two hours later, by a violent pain which extended to the extremities of the fingers. Fever then set in, and lasted two days, and a circumscribed abscess formed, which, on dilatation, gave issue to laudable phlegmonous pus. At the end of two weeks the wound was closed and all pains had ceased.

The next case was that of a man who had an indolent lipoma, nearly the size of an orange, about the middle of the back. A 10 per cent. solution of nitrate of silver was used, and of this 20 drops were injected in the centre of the tumor; an abscess formed, which after a week opened spontaneously, discharging a considerable quantity of pus. The tumor was reduced to nearly one-half; two more injections, of 10 drops each, were then made, before the first abscess closed, and by the time this was healed the lipoma had entirely disappeared.

The third observation was in the case of a woman, 29 years old, multiparous, who had on the right breast a hard, elastic tumor, occupying the periphery of the gland, and about the size of a walnut. After careful examination, the case was pronounced one of mammary fibroma. The patient having refused ablation, 15 drops of pure tincture of iodine were injected in the centre of the tumor; this caused a violent pain, which lasted about an hour, but no inflammation nor œdema. During a month dissolving ointments were applied, and the tumor decreased nearly one-half; another injection was now given, followed by a slight inflammatory reaction, and the almost total reduction of the tumor.

Congenital Abnormality in Production of Hair.

At the International Medical Congress last summer (*Archives of Dermatology*), Dr. Thin, of London, described a case of congenital abnormality in the production of hair on the scalp, in a girl, aged four, whose hair, although normal in quantity, was defective in its formation, and was reported to have been so since infancy. The hairs were rough and crisp to the touch, varied in length from a fraction of an inch to little over an inch, and broke off in numbers when the scalp was firmly rubbed. There was continual formation and continual breaking of the hairs. When the hand was passed over the head of the child, the sensation experienced was like that felt on

rubbing a pig's skin against the direction of the hairs.

Professor Kaposi (Vienna) had seen two cases of the same kind. In one, a boy four years old, there were present features of lichen pilaris, especially on the neck. The affection was congenital, like ichthyosis. The second case was exactly similar. There was a gradual improvement in the first case, under stimulating local treatment.

M. Vidal (Paris) had also seen similar cases, but twice only. The sebaceous system was poorly developed in them, and the affection was probably due to defective development of the sebaceous glands. Breaking of the hairs was also found in seborrhœa sicca.

Dr. Unna (Hamburg) had under his care a case of the same affection in a young lady. It was in this instance limited to the vertex, having come on after great mental depression. As in alopecia, there was dryness of the skin and coarseness of the hair, with hardness of the scalp. He thought it like scleroderma circumscripta. It got better under sulphur ointment.

Dr. R. Liveing had seen one similar case, which had existed from earliest infancy.

Dr. Bulkley (New York) had seen one case, in a boy aged six, in whom there was also marked lichen pilaris on the arms.

The President remarked on the various alterations of the hair, and referred to its occasional wiry condition.

Night Sweats in Phthisis.

In the Glasgow *Medical Journal* for March Dr. John M. Young says: The drug agaricus, whose influence in checking night sweating was lately brought into notice in this country by Dr. Wolfenden, of Charing Cross Hospital, has been used pretty extensively during the past few weeks in Dr. Gairdner's wards in the Western Infirmary, with extremely satisfactory results. The drug, derived from the common toadstool, is a light brown, bulky, insoluble powder, with a very nauseous taste, and on this account cannot very well be administered as such. A tincture of the strength of ten grains to the drachm was found quite satisfactory, a proportionately smaller quantity of the drug in this form being required to produce equal effects. Finally, a principle, which may perhaps be called *agaricine*, crystallizing in long needles, like those of strychnine and other alkaloids, was extracted and administered in pill form, each pill containing one-half of a grain, and one or two forming a dose, according to circumstances. This is perhaps the most acceptable form in which to administer the drug, and the therapeutic effects obtained have been practically the same. These therapeutic effects are classed as follows:—

1. Night sweating becomes proportionately lessened, according to the amount of the drug administered; and, if sufficient doses be given, becomes effectually checked or prevented, according to the time of administration.

This was observed to be the absolute rule in all moderate cases of phthisical night sweating where it was tried, and in one case, where the sweating was colliquative, agaricus brought the sweating within moderate limits; though probably, if sufficient doses had been given, it might have cut it completely short. In other cases of sweating not dependent on phthisis the drug was found to work well; indeed, its most notable effect was observed in the case of a patient who had had sweating of the right side of his body and right leg persistently, at night, for eight months, and in which a dose of ten grains stopped the symptom for a night almost at once.

Indeed, in the quickness of its action, agaricus resembles atropin. Like atropin, too, the effect is not permanent. In some cases, during the second night, sweating was found to be reduced below its average amount, or even entirely absent; but in the majority of cases, unless the drug was repeated, sweating returned as intensely as ever, and repetition of the drug during a considerable period does not appear to lead to any permanent result. Observation rather points to the necessity of gradually increasing the dose under such circumstances.

2. The effect of the drug against sweating is not more marked than its effect in promoting sound sleep, and relieving troublesome cough, especially of phthisis. This is the most notable fact to the patients themselves, a gradually increasing feeling of drowsiness following its administration in most cases, and this I can confirm from personal experience. In one case in particular, characterized by extremely troublesome and painful coughing during the night, to combat which numerous remedies had been tried with little or no effect, after the first large dose of tincture of agaricus this symptom became entirely subdued, and the patient had sound sleep. Her cough has since been effectually kept under by the remedy. In another case of severe spasmodic cough, of nervous origin, agaricus gave considerable relief when first administered.

The antihydrotic and soporific effects of the drug are probably distinct from one another, and not to be related as cause to effect, since, in some of the cases observed, sweating was always complained of as occurring *during* sleep, the body being covered with perspiration on awaking. Cessation of cough may, however, be the result of the soundness of sleep.

3. Strict investigation seemed to show that the drug has considerable influence in reducing the temperature, in cases of phthisis at least, where the fever is unstable, as much as two degrees of a fall having been observed within half an hour after administration of $\frac{1}{12}$ of a grain of agaricine. Such a marked result was not always obtained by repetition of the experiment in different cases; but the fall observed in this way averaged 1.4°, and had its expression in a relieved feeling on the part of the patient.

Along with the effect on temperature, it may be noted that the rate of the pulse becomes usually reduced to a corresponding degree, but this effect has not been invariably noticed.

Reasoning from the analogy of the effect of nitrite of amyl on the blood pressure, I compared, in five or six cases, sphygmographic tracings immediately before and half an hour to an hour after the administration of the drug. I was not surprised, however, knowing the difficulty of registering fine differences in pressure by means

of a sphygmograph, to find in most cases no discernible difference. In one case, nevertheless (probably one of more than usual susceptibility to the remedy), several trials showed that the tracings of the pulse, which, when uninfluenced, had a decided leaning toward the characters of dicrotism, after the administration of twenty grains, came to assume characters pointing to greater tension, the aortic notch diminishing or entirely disappearing. The rate of the pulse at the same time fell from six to twenty beats. These observations may have some bearing on the rationale of the effects of the drug, but they are far from free from the chance of fallacy.

Since the administration of the tincture was begun, complaints of sickness were only heard in *one* case, in which the drug had been given over a considerable period. Diarrhœa was only occasioned once, and that in a case where this symptom recurred at intervals, independently of the drug. Its laxative action, indeed, was noticed by some patients as very satisfactory. Dr. Wolfenden found that such diarrhœa could be averted by combination with one or two grains of Dover's powder. No other bad effects have been observed.

Good results have also followed its use in some of the other wards in the Western Infirmary. A sufficiency of the principle of the drug has not yet been obtained to make up a solution for hypodermic injection. Probably the effects following on this method of administration will be even more decided.

No comparative trial of its merits as against other medicines with similar effects was made, the object sought for having been rather to confirm it as a drug at once innocuous and thoroughly to be depended upon against night sweating when administered by the mouth.

Dr. Wolfenden's remarks on this point may be quoted in conclusion: "Having made extensive trial of those remedies commonly in vogue for checking the debilitating night sweats of phthisis, I have found many sadly wanting, and only *one* —viz., atropin—that yielded really excellent results. Given in $\frac{1}{70}$ of a grain doses it rarely fails. But atropin is a drug of great power, and capable of producing great physiological effects; and, although accidents are very rare, such an accident as an overdose might easily occur, and dispensing is not always faultless. . . . . The complete success of agaricus has led me to consider it of value equal to atropin, and superior to atropin, from the fact that it is quite innocuous. . . . . I believe it to be a preparation worthy of extensive trial, and of such equal efficacy with atropin that it may supplant it."

Homicide by Infection.

Dr. A. D. Leith Napier thus writes to the *British Medical Journal*:—

Your pertinent article on Homicide by Infection, in the *Journal* of February 4th, has suggested to me the propriety of addressing the profession, through the *Journal*, regarding certain generalities connected with the subject of puerperal septicæmia.

There is, unquestionably, some want of unanimity in the minds of the profession on the question what puerperal fever really is. That it is not, in the great majority of cases, one specific disease, is allowed by all, or by nearly all. That it is never a specific disease, is held by most authorities of repute. That there is a specific disease, if we desire to abolish the name puerperal fever, say a distinct septicæmia, which, at times, is liable to become epidemic, is still believed by some who have carefully investigated recent outbreaks.

Among many, the late Drs. Fleetwood Churchill, and Alfred McClintock, and Dr. Matthews Duncan, have stated the non-necessity for a practitioner who has charge of cases of puerperal septicæmia ceasing from obstetric practice. Others have strongly insisted that, in the event of two or more cases of puerperal septicæmia occurring consecutively in practice, a lengthened period of interruption from attendance in midwifery is absolutely imperative.

The discussion, in 1875, in the London Obstetrical Society, beyond arriving eventually at an opinion that the disease called puerperal fever was not a disease, but, as had been previously stated by Dr. Farre and others, many blended together, in no way advanced the pathology of the affection. Since then, little more has been done. One notable exception is Dr. Matthews Duncan's elaborate demonstration, that puerperal fever is non-epidemic. My own papers, contributed to the *Obstetrical Journal* (July to December, 1880), endeavored to establish various propositions. 1. At certain times large numbers of parturient women are attacked with fever, followed by secondary evils. 2. This fever is not solely dependent on septic material conveyed manually. 3. It is not dependent on erysipelas. 4. It is not ordinary septicæmia or pyæmia. 5. It is communicable by contagion. 6. As in other fevers (*e.g.*, typhus, typhoid, scarlatina), complications frequently appear, varying in their nature, as the constitution of the patient, and the surrounding hygienic arrangements may vary. 7. Like other blood-poisons, it is most virulent in hospitals, or where large numbers of lying-in women are crowded together. 8. It is a distinct disease from its complications—peritonitis, metritis, öophoritis, phlegmasia, etc. 9. It is infectious to the fœtus in utero, or the new-born child, as are smallpox, measles, etc. 10. The lower animals are simultaneously affected. 11. When the disease runs its normal course, the post-mortem appearances are not more inconstant than in other fevers. 12. In the course of an epidemic, like all general epidemics, "a wave" is usual; after it has become epidemic, incoming strangers are more liable to infection than habitual residents, etc.

These views were not the outcome of theoretical musings, but deductions derived from a close study of the clinical aspects of the question. They are offered for the consideration of all who care to accept clinical work as the basis of a scientific distinction in disease. I am aware that improvements might be made on my method of statement, but refer the readers of your *Journal* to the above-mentioned cases and extended remarks for fuller particulars. The inquiry, originated by Dr. Braxton Hicks, in the *British Medical*

Journal for January 22d, 1876, most unfortunately was not taken up by the members as it should have been. A more important inquiry than "What is the requisite quarantine after attendance on puerperal fever?" could not well be originated. Except the replies of the late Dr. F. Churchill and mine, in the *Journal* for March 25th, 1876, no other was forthcoming.

The important experiments recorded in recent numbers of the *Journal*, by Dr. Braidwood and Mr. Vacher, seem to show that septic infection may result from normal lochia; and that, under certain conditions, this may be enormously increased in potency. For clinical purposes, these experiments prove almost too much, as, with a lacerated perineum, which has been demonstrated by Snow, Beck, Duncan, etc., to be a most common condition after labor, puerperal fever ought, theoretically, to occur much more frequently than it does. The predisposing causes of bad general health, physical and mental, etc., must naturally be deemed important; but, whatever differences may pertain regarding the causation of the condition, theoretically, practically the individual responsibility of an attendant, in disseminating infection, must be of the greatest importance. If midwives are to be registered, and entrusted with such powers and privileges as is proposed by the Parliamentary Bills Committee, and reported in your issue of February 11th, it is highly desirable that no uncertainty should remain concerning these momentous questions of quarantine or no quarantine; of disinfection, and what disinfection; of culpability or criminality, or not? To determine these points, I think it would be advisable to obtain a series of short articles, of as practical bearing as possible, from members of the Association; and to refer the matter to the Investigation Committee, or a special committee, who would collect evidence and statistics, which might be afterwards drawn up and circulated throughout the profession. Unless the members really interest themselves, and give as full information as possible, the labors of any committee must needs be futile. In addition to the etiology, recent methods of treatment, *e.g.*, quinine, carbolic acid, sulpho-carbolates, Warburg's tincture, aconite, etc; prophylaxis by disinfectants, carbolic acid, permanganate of potash, turpentine, iodine, etc., might be embodied in the inquiry.

I have only outlined what I might have dwelt on at much length, but hope the matter may prove sufficiently attractive to be taken up heartily by the members.

Strangulated Hernia; Complications; Recovery.

From the *Medical Times and Gazette* we note the following case, which occurred in the Liverpool Royal Infirmary, under the care of Mr. Rushton Parker: John D., aged thirty-four, a laborer, was admitted on October 8th, 1880, on account of a right inguinal hernia, five days old, and two days strangulated. Mr. Harrison reduced the hernia the same day, at his visit, but was not perfectly satisfied with the feel and look of the parts; so, being about to leave town for a few days, he explained his impression to Mr. Parker, and requested him to watch the man, in the event of renewed emergency. The following day vomiting had occurred, the patient was uneasy, the site of the hernia was a little swollen, but evidently devoid of contents, and the neighborhood tender. But the pulse was about eighty and the temperature about normal. No wind had now passed for three days; but there was no distention or hardness of the belly. Water and filtered beef tea were alone permitted. Twenty-five or so drops of laudanum were given by the mouth, to be repeated night and morning, unless obviously not required. He continued fairly comfortable and quite contented under this treatment for the following days, showing no change except an increasing fullness of the belly, with disappearance of the tumefaction over the inguinal canal; the pulse and temperature also remaining about the same. No wind was passing; but no abdominal symptoms were apparent, except a tympanitic condition, with its consequent and increasing discomfort. The foot of the bed was elevated and the relief to the abdomen was appreciated but the size of the belly was increasing, and its tension too. Thirst was, of course, experienced, and it is not unlikely that it was too frequently and too copiously slaked.

On October 14th, the sixth day after reduction, the abdomen was punctured with an exploring trocar and canula, in three places, some fœtid gas escaping. Though the issue was small the tension was lessened, and the patient was pleased at the relief. The punctures were repeated on the two following days, and the distention thus kept within bearable limits. Then a copious liquid stool followed, the belly flattened down, and the patient continued to do well; the diet being carefully restricted to bread, potatoes, and beef tea or tea. The bowels remained sluggish after his diet was increased, and an occasional hot water enema was used after they appeared to be otherwise sound and free from tenderness; but a flabby and bagging condition of the lower abdominal front persisted almost throughout the convalescence. A local complication arose in association with the punctures, and prolonged the confinement to bed, though fortunately without masking the uninterrupted good progress recognized in the abdominal functions. Some fæces occasionally escaped by the trocar, which was protected by carbolized oil, and manipulated with deliberate care, to try to avoid intra-peritoneal effusion, with success. But a little escaped into the subcutaneous fat on the first day of puncture, and led immediately to a small, putrid abscess, which was opened, but not properly disinfected or drained at once. There followed, in consequence, a serpiginous phlegmon around the abdomen and flank, which was then progressively incised and treated with terebene and oil, washed through, and covered with gutta-percha tissue without rags. Some subcutaneous sloughs occurred, but were thus speedily disinfected, and rapid healing followed their issue. On one of the few days on which the bowels were punctured, at the height of their distention, the tongue became dry and the breath sweet. Whatever be the real significance of the latter feature, one could not help recalling its usual association with collapse and other forms of threatened or impending extinction, nor resist

the fear that failure was, after all, about to result. But as very little opium had been used—perhaps too little, considering the increasing flatulence—an extra dose was now given. Not many hours later came the copious evacuation, preceded by increased comfort, attributed to the opium.

Note.—The persistence of symptoms, after the release of the hernia, was regarded as the not unnatural result of an acute strangulation; yet it was not easy to decide between that, a functional maiming the effect of a bruise, and the physical constriction of a possible reduction *en masse*. The case forms an interesting and instructive contrast with No. 1 (February 4th, 1882), and it is obvious that but little was wanted in either patient, at the critical time, to turn the scale against him.

Puerperal Hemorrhage.

In the *American Practitioner*, Dr. Theophilus Parvin records the following case, in which he obtained most excellent results from hypodermic injections of ether:—

Mrs. K., thirty-seven years of age, was delivered of her third child at 7 A.M. The physician in attendance having failed to remove the placenta, and excessive hemorrhages occurring, I was sent for and saw her at 9 A.M. I found her almost pulseless, countenance with a death-like pallor, bathed with perspiration, restlessly tossing her arms, complaining that she could not see, that she was dying. Whisky and ergot had been given to her freely, and caused occasional efforts of vomiting. My first step was to remove the pillow and bolster from under her head, and to have the foot of the bed raised so as to facilitate the flow of blood to the anæmic brain. Next, placing one hand on the abdomen, I could not feel the uterus. It was without form and flaccid as the abdominal wall itself. The other hand was introduced into the vagina, and from the vagina into the uterine cavity. I found that the cord had been torn loose close to the placenta, in vain efforts to extract the latter, which was free in the uterine cavity. The uterus was completely relaxed, as flabby and soft as a "piece of wet tripe." In vain I sought, by compression and friction through the abdominal wall with one hand, and by movements of the other within the uterine cavity, to excite contractions. I then removed the placenta and injected water at the temperature of 110°, but still there was no response from the muscular fibre of the uterus, although the patient complained of the heat of the water as it flowed out through the vagina, and her exhaustion became still more alarming.

Remembering the very favorable results obtained by Hecker, in uterine hemorrhage, from hypodermic ether, I injected twenty drops of sulphuric ether, and repeated the operation at intervals of from five to ten minutes, until one drachm and a half of the liquid had been thus introduced. Meantime direct stimulation of the uterus by friction and compression externally, and by a hand in the uterine cavity, was continued, and about the time the last hypodermic was used contractions first manifested themselves, and within half an hour the uterine retraction was nearly as complete as is observed after normal labor.

Of course, the patient's convalescence was very tedious. It was three weeks before she could sit up in bed without fainting. Nevertheless, her recovery was uninterrupted.

After briefly discussing the various local measures for arresting hemorrhage, Dr. Parvin concludes by saying, "But, whatever method may be resorted to for the arrest of the hemorrhage, it is of the first importance that the patient should be restored from her profound prostration. Among the means of this restoration probably none is so prompt and effective as hypodermic ether."

Pigmented Mole of Abdomen, Side and Back.

Dr. William H. Bull reports the following curious case in the *British Medical Journal*:—

L. C. was born on August 4th, 1880. Her parents are both strong, robust, and healthy-looking people, with good family history. The husband, twenty-four years of age, is employed as a mechanic in some large works. The mother, twenty-one years of age, had been married three years, and had one male child perfectly developed. When pregnant two months and a half with this, her second child, the mother states that she was frightened by a large black dog, which lay on the road while a cart passed by; and she, thinking it was a child about to be run over, screamed out, when the dog rose suddenly. There is no other history of a fright. The mother is reported to have always been passionately fond of dogs, and would nurse them for hours on her lap.

On August 4th, 1880, she was attended by a midwife; and, after an ordinary labor, was delivered of this female child. The case was brought to me at the hospital when a fortnight old. I found the greater part of the skin of the abdomen, right side, and the whole of the back, from a line drawn between the axilla above down to the anus below, and extending down the right thigh, as far as the junction of the upper with the middle third, hypertrophied, superpigmented, and covered with hair one inch in length. The right labium was greatly enlarged, forming quite a flap, which almost completely covered the vaginal orifice. On every part of the body, from the crown of the head to the soles of the feet, there were a number of minute patches of pigment, varying in size from the point of a pin to a very small split-pea. The skin over these parts was perfectly smooth, and free from hairs. In all other respects, the child was well-developed.

In August, 1881, with the exception of a little stomachic and intestinal irritation at times, the child had enjoyed perfect health. Several more minute spots of pigment had appeared in different parts of the body, and some of the original ones had increased somewhat in size. The hypertrophy of the thigh had extended downward three-fourths of an inch; but the abdomen, side and back, remained unaltered.

A case of this kind becomes one of surgical curiosity, rather than of surgical importance; and calls for but few remarks. I have been unable to find any case on record exactly similar to this; but specimens of less severity, and

more limited in extent, have been reported. Such cases open out a wide field for discussion upon the important subject of "maternal impressions."

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——On the Brains of Criminals. By William Osler, M.D., Montreal. Reprint from the *Canada Medical and Surgical Journal*, February, 1882.

——"Rande" (Charles C. Scott); a medico-legal record. By one of the expert witnesses. Reprint from the *Alienist and Neurologist*, April, 1882.

——The Use of Constitutional Remedies in the Treatment of Ear Diseases. By Samuel Theobald, M.D. Reprinted from the *Medical News*.

——On some points in the Etiology and Pathology of Ulcerative Endocarditis. By William Osler, M.D., Montreal. Read before the International Medical Congress.

——Some points regarding the Diagnosis of Uterine Anteflexions and Anteversions. By Clifton E. Wing, M.D., of Boston. Reprinted from the Boston *Medical Journal*, February 9th, 1882.

——Moral (Affective Insanity); a Plea for its Retention in Medical Nomenclature. By C. H. Hughes, M.D., of St. Louis. This is an abstract of a paper presented by the author to the International Medical Congress, 1881.

——Case of Obliteration of the Portal Vein (Pylephlebitis Adhesiva), by William Osler, M.D., M.R.C.P. Lond., Professor of the Institutes of Medicine, McGill University, Montreal, comes to us as a reprint from the *Journal of Anatomy and Physiology*.

——Note on the Microscopic Appearances presented by the Blood of Scarlatina and Typhoid Fever. By J. H. Kidder, Surgeon U. S. Navy. This paper comes to us from the office of the Surgeon General of the Navy. It is very interesting, and is accompanied by six photographic illustrations.

——Gunshot Wounds of the Abdomen; Fecal Fistula; Spontaneous Closure; Recovery; with remarks on Treatment; including a further consideration of the action and applications of quinine. By A. Sibley Campbell, M.D., Augusta, Ga. Reprinted from the Transactions of the Medical Association of Georgia.

——We have received the Third Annual Report of the State Board of Health, of Illinois, with the official register of physicians and medicines. The large States of the West are preparing health reports that are superior in completeness to those of our Eastern cities. Among other interesting statements, this report contains a complete alphabetical list of the medical colleges whose diplomas are recognized by the Board, with a table showing the course of study, fees and requirements.

BOOK NOTICES.

A Clinical Handbook on the Diseases of Women. By W. Symington Brown, M.D., member of the Gynæcological Society of Boston, Fellow of the Massachusetts Medical Society, etc. pp. 247. New York: William Wood & Co. 1882.

The author does not claim that his production is a text-book; he desires merely to furnish to physicians a small guide in the management of the most common diseases of women. The book is made up of well selected information from standard authorities, interspersed with cases from the experience of the author.

Illustrations of Dissections; in a series of original colored plates. By George Viner Ellis, Professor of Anatomy in University College, London, and G. H. Ford, Esq. Vol. II, pp. 217. New York: William Wood & Co.

This book, the first volume of which we have already noticed, constitutes the February number of Wood's Library of Standard Medical Authors. It is a very well illustrated and a very valuable book.

Manual of Dental Surgery and Pathology. By Alfred Coleman, L.R.C.P., etc. etc. Thoroughly revised and adapted to the use of American Students and Practitioners. By Thomas C. Stellwagen, M.A., M.D., D.D.S., etc. pp. 408. Philadelphia: Henry C. Lea's Son & Co. 1882.

A very well prepared and revised manual, that will no doubt prove of service to progressive dentists.

Annual Report of the National Board of Health, for 1879. From the Government Printing Office, Washington.

This volume is received, with the compliments of T. J. Turner, M.D., Secretary of the Board. It is a most valuable book, full of interesting and instructive statistics and maps.

Physician's Perpetual Visiting List and Pocket Reference Book of Medicine. By D. Tod Gilliam, M.D. J. Wendell Cole, Chicago. Illustrated. Price $1.00.

A very well arranged little book; it will answer the purpose designed very well.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

PROFESSOR SAMUEL D. GROSS.

The resignation of a teacher so distinguished, and his retirement from the active duties of instructing the young aspirants for medical degrees, is worthy of more than passing notice. For many years Professor GROSS has been cheerfully and universally accorded a preëminent position among the surgeons of America. His reputation has become international, and he is looked upon, wherever our science is recognized and appreciated, as one of the greatest living surgeons, one whose name will remain alive after the body shall have resolved itself into clay; a name that will be treasured and revered for ages to come, as we of to-day are wont to cherish the memories of Æsculapius, Hippocrates, Galen, Vesalius, Hunter, or McDowell.

Truly Professor GROSS is a great man. Great in everything that tends to make a man a MAN. Not only does he excell in his own particular study and pursuit, but also does he stand pre-eminent in all the requisites of a true and *gentle* man.

Born near Easton, Pa., on the 8th of July, 1805, he received a classical education at the Wilkesbarre Academy and the high school at Lawrenceville, N. J. He commenced the study of medicine with Dr. Joseph K. Swift, of Easton, and was subsequently, for two years, a private student under Prof. George McClellan. He graduated from the Jefferson Medical College in 1828, and began practice in Philadelphia, employing his leisure hours in close study, and in the translation of several standard French and German medical works, which were published. In 1830 he issued his first original work, "Diseases and Injuries of the Bones and Joints," in which particular mention is made of the use of adhesive plaster as a means of extension in the treatment of fractures, now so generally employed by surgeons of this and other countries. During the same year he returned to Easton. In 1833 he became Demonstrator of Anatomy in the Medical College of Ohio, at Cincinnati, and two years later, Professor of Pathological Anatomy in the Medical Department of the Cincinnati College. Here he delivered the first systematic course of lectures on morbid anatomy ever given in the United States, and while thus occupied composed his "Elements of Pathological Anatomy," the first methodical treatise on the subject ever published on this side of the Atlantic or in the English language. After four years he accepted the Chair of Surgery in the University of Louisville. For ten years he labored in this lecture room, and then, in 1850, resigned, to accept a similar professorship in the University of New York, just vacant by the retirement of the venerable Dr. Mott. At the end of the first session he withdrew, and at the earnest solicitation of his former colleagues, returned to his Louisville chair. In 1856 he was elected Professor of Surgery in the Jefferson Medical College, of Philadelphia, which chair he has continuously occupied until the present time.

Dr. Gross is a very voluminous author; in addition to the works already named, he has, among others, written his "System of Surgery," upon which his posthumous fame will most probably mainly depend: it appeared in 1859, has passed through five editions, the last, issued in

1872, being thoroughly revised and brought up to the existing state of the science. It was translated into Dutch, and published at Nieuewdiep, in 1863, and is the most elaborate and exhaustive work on Surgery ever written by one man. He edited a large work on "American Medical Biography," was one of the founders and chief editors of the *North American Medico-Chirurgical Review*, and is the author of numerous addresses on medicine, surgery and biography, of a "History of American Medical Literature," and of a "History of the Progress of American Surgery during the last Century." He is a member of the American Philosophical Society, of numerous medical societies in the United States, of the Imperial Medical Society of Vienna; of the Medical Society of Christiana, in Norway; Royal Medical and Chirurgical of London; Medico-Chirurgical of Edinburgh; Medical Society of London, and British Medical Association, to which, on two occasions, he was an accredited delegate. He was one of the founders and early presidents of the Kentucky State Medical Society. While in Louisville, he published an elaborate and exhaustive "Report on Kentucky Surgery," in which he first established the fact that the late Dr. Ephraim McDowell, of Danville, in that State, was justly entitled to the honor of being the father of ovariotomy, until then erroneously ascribed to other surgeons. Shortly after settling in Philadelphia, he founded, in conjunction with Dr. Da Costa, the Philadelphia Pathological Society, of which he was the first president. In 1867 he was elected president of the American Medical Association and in April, 1870, presided at the Teachers' Medical Convention, held in Washington, to consider the subject of medical education. In June, 1870, he was chosen president of the Pennsylvania State Medical Society. In 1872, the University of Oxford, at its one-thousandth commencement, conferred on him the honorary degree of D.C.L.; that of LL.D. he had previously received from Jefferson College. He was unanimously elected president of the International Medical Congress which met in Philadelphia, in September, 1876.

Dr. Gross has always been a warm and decided advocate of professional progress and of a higher standard of medical education. Systematic and economical of time, he has, while punctually fulfilling all engagements as professor and practitioner, been enabled to maintain his early habits of earnest study, to keep thoroughly informed in medical and general literature, and to become a voluminous author. Large portions of his works have been composed while riding about the city in his daily professional routine. Such is a brief sketch of the life of this great and good man. It should be familiar to every student and young practitioner of medicine, since it would be impossible to select a better model, or to follow in the footsteps of a more perfect medical life, than that of the venerable professor who has just, to the regret of the universal profession, retired from public life.

GOVERNMENT CONTROL OF MEDICAL EDUCATION.

In the short space of an editorial, it will be impossible to adequately present the points involved in this extensive question. We desire merely to turn attention and thought in this direction. So long as schools and professors are dependent upon fees from students, for support, so long, necessarily, will the standard of medical education remain low. Such schools cannot afford to reject candidates. Such action would be throwing money away, and it is altogether too utopian to expect any man of mature years to be so reckless. Were the government to take control of medical education, as they have done with the postal, and ought to do with the telegraph service, the case would be far different. By establishing medical colleges, as mints are now located, at points deemed suitable, by installing a well paid corps of professors in each, and by establishing one final board of examination for all, said board being the only body in the country capable of conferring degrees, the standard of medical education could be readily elevated to any desired level. By refusing to grant charters to any individual colleges, quacks, under the guise of regular graduates, would be impossible. We know that the standard of ex-

amination for admission into the medical corps of the army and navy is much above that required for the reception of a degree from the average medical college. This is simply because the examiners in the former cases have nothing to make or lose by the candidates; hence, they can perform their duty honestly and conscientiously. With government control of medical schools, the same condition of affairs could be brought about. These few words form merely a prelude; we shall, in the future, discuss this vital problem more in extenso.

VIVISECTION.

Although so much has been already said on this subject, yet we cannot but rejoice when we find men of eminence fighting anti-vivisectionists with their own weapons. It has been frequently commented upon, that persons who view with horror the scientific mutilation of the lower, when the object to be attained is the benefit of the higher, class of animals, think it perfectly proper and legitimate to hunt to death and seriously wound poor inoffensive animals, with no nobler aim in view than merely to gratify their passionate inclination for sport. The best answer to anti-vivisectionists that we have for a long time heard, we quote in the following words from a daily cotemporary. Such arguments need no elaboration or comment; they plainly teach that "*people who live in glass houses ought not to throw stones:*"—

"Some little time ago Miss Frances Power Cobbe, who has so identified herself with the cause of anti-vivisection, called on a distinguished man of science, in London, to endeavor, by persuasive speech and *viva voce* argument, to gain him over to her cause. Three points were observable in Miss Cobbe's outward presentment, namely, she had an ostrich feather in her bonnet, a bird of paradise on or near her muff, and she carried an ivory-handled umbrella. Consequently, the distinguished man of science replied as follows: 'Madam, charity begins at home; when you have given up wearing ostrich feathers, which are plucked from the living bird, causing the most exquisite pain, and birds of paradise, which, in order to enhance their beauty and lustre, are skinned alive—when you have abjured the use of ivory, because you know that the tusks are cut out of the dying elephant's jaw—then, and then only, come and upbraid me with the cruelty of my operations. The difference between us is, madam, that I inflict pain in the pursuit of knowledge, and for the ultimate benefit of my fellow creatures; you cause cruelty to be inflicted merely for your personal adornment.'"

PUERPERAL SEPTICÆMIA.

In our *Periscope* we present a long communication on this subject, from the *British Medical Journal*, because we deem it a question worthy of the most careful thought and consideration of the profession. We have had a sad experience with this vague and indefinite condition, usually designated as "*puerperal fever*," having lost, during an epidemic in the Philadelphia hospital, more than thirty cases, out of a total of seventy-five lying-in-women. No medication seemed to have any influence on the terrible malignancy of the disease, which usually terminates fatally, within from three to four days of its onset. The most prominent symptoms, besides high temperature, were persistent and absolutely uncontrolable vomiting and purging; the patients really dying from exhaustion.

Realizing that knowledge of this terrible puerperal condition has not increased in the same ratio as our acquaintance with other diseased conditions, and considering how vague is our knowledge of its true etiology, therapeutics and pathology, we desire to direct research in this direction, and would urge our readers to carefully note clinically all that may tend to throw light on the history of this terrible affliction, and when they have made any valuable observations, to make them public.

Notes and Comments.

Congenital Club-foot.

The *Lancet*, editorially, offers the following sensible and valuable suggestions:—

It is unfortunate that so much of mystery and specialism hangs about the treatment of club-foot. It is too generally thought that it consists solely in tenotomies and the application of complicated and expensive shoes of various kinds, which none but the specially initiated can understand. And for this reason cases are often left untreated just when simple treatment would be most quickly successful; for club-foot, like every disease and deformity, is more amenable

to treatment in its early, uncomplicated stages, and many a case which in later years is cured only after long and wearisome treatment would have been comparatively easily dealt with in its earliest stages. The great objects to be attained in all cases of club-foot are to replace the part in its normal position, with the help of tenotomy where necessary, to retain it in that position for a sufficient length of time, and to exercise and stimulate the development of the weakened muscles. This can all be done in congenital club-foot from the earliest days, and ought to be commenced at once. The hand is the proper instrument to correct the deformity, and a plaster-of-paris splint just strong enough for its purpose the best means of maintaining the foot in its proper place. This splint, if made after the Bavarian pattern, can be removed every day, for the foot to be rubbed and electricity applied; or the more common form of plaster-of-paris splint may be removed for the same purpose every two to four weeks. If practitioners would treat their cases of club-foot in this way from the very first, many would be almost if not quite cured before the child began to walk, when the difficulty of treatment is necessarily increased.

Miners' Anæmia.

The *Lancet* says, in a communication to the Académié des Sciences, M. Perroncito has described an anæmia which occurs among the miners of St. Etienne, and which resembles closely the disease observed among the workmen at the St. Gothard tunnel, and found to depend on the anchylostoma duodenale. Examination of the stools of three patients at St. Etienne revealed in each large numbers of the ova of anchylostoma. This observation proves the identity of the two diseases. The same parasitic affection has been met with among the miners of Schemnitz. "Miners' anæmia" is thus brought into the class of preventable maladies, since it may be prevented or cured by the employment of substances which have been found capable of destroying the ova either outside or within the human body. The larvæ do not develop in the intestine, but in the fecal substances after dejection, and penetrate the organism by the air or water after their development. In no stage can an organism resist a temperature of 50° Centigrade, and the larvæ are quickly killed by a concentrated solution of chloride of sodium, in sulphuric or hydrochloric acid, in ethylic alcohol, or in one to five per cent. solutions of carbolic acid, and in one-half per cent. solution of thymic acid, and in ethereal extract of male fern. By any of these means the fecal larvæ can readily be destroyed. The male fern given internally is always effectual, even in a single dose. Thymic acid may also be given by the mouth, for the same purpose.

Treatment of Snake-bite.

Dr. Vincent Richards (*Indian Medical Gazette*, January) offers the following suggestions as to the treatment of snake-bite: 1. In the case of the bite being on a limb, a ligature should be at once applied above the bitten part, care being taken that it is sufficiently tight to prevent any blood being taken up into the general circulation from the distal end; give a full dose of opium (forty minims of the tincture, or half a grain of morphia) hypodermically. 2. Inject hypodermically, into the bitten part, a solution of the permanganate (one grain to a drachm), and well press the part with the fingers. 3. Open a vein below the bitten part, and wind round the limb an elastic bandage, so as to exsanguinate the limb below the bitten part. 4. Cut through the bitten part, and, when dry, apply pulverized permanganate, and then loosen the ligature. In the case of a person bitten on the trunk, any treatment, however prompt, may be useless; but it would be well to inject the part with the permanganate, and give a full dose of opium. "It may not be generally known to the members of the profession that a poisonous bite may be easily ascertained by cutting through the punctures into the areolar tissue beneath, when, if a red-currant-jelly-like appearance be observable, the bite is poisonous. The merit of pointing out the diagnostic value of this local appearance is due to Dr. Wall."

Poisoning by Nitrate of Potash.

In the *British Medical Journal*, Dr. Wolstenholme reports the following case. He was called to see a farm laborer, who complained of intense pain in the stomach. It was constant and of a burning character. On inquiry, it was found that he had taken an ounce of *salts*, about 7.30 in the morning. The *salts* did not taste quite the same as usual, but they were not sour. As soon as he had taken the salts, he felt the intense pain in his stomach. He felt sick, but did not vomit until four hours afterwards. His pulse was 56, full and strong; pupils normal, tongue moist, with white fur down the centre. No excoriations about the mouth or any signs of an irritant. An opiate was ordered to be taken

every hour, with hot applications to the epigastrium. Late in the afternoon he was called again. The same symptoms were presented. The patient now said he thought it was *saltpetre* he had taken, and this was subsequently demonstrated to be the case.

He was given a free emetic and a copious warm water enema, with one-fourth of a grain of morphia in pill every three hours. After the emetic and enema had acted, the patient was much easier, and made a gradual and steady recovery.

Disinfection of Urine.

In the *Medical Annals*, Dr. F. C. Curtis states, hydrate of chloral has the property of disinfecting urine. In August last he received a specimen of urine, four ounces, containing five grains of chloral to the ounce. No special care was taken to facilitate its preservation. It has been simply corked, and has been several times opened. It is now perfectly transparent, of a clear amber color, and has a fresh, urinous, slightly balsamic odor. A slight semi-flocculent deposit covers the bottom of the vial. The chemical analysis is identical with the notes made when it was recent: sp. gr. 1.015, acid, albumen one-fourth. The preservation of the albumen is a marked test. On microscopic examination, the epithelial cells are as perfect as in recent urine. No casts were noted and none are now seen. The specimen seems to be quite the same as when freshly voided, and is manifestly instructive and of considerable interest.

Mask Treatment of Eczema.

In the St. Louis *Medical and Surgical Journal*, Dr. R. W. Wilcox says, eczema of the face and head, so common in children, in many cases fails to be relieved, for the simple reason that the applications are not closely applied to the diseased surface. To remedy this deficiency a mask is here in use, a piece of cloth, with holes for the eyes, nose and mouth, with slits for the ears, to assist in keeping it in position. The ointment is to be thickly smeared over the mask, and it is to be worn constantly, only being removed as lotions are being applied. This treatment effectually prevents the scratching, which so thoroughly thwarts all endeavors. Any ointment can be used, but for the most part, diachylon, very carefully made, is selected. In something the same way a skull cap can be made, the inside of which, smeared with the ointment, can be used for eczema of the head.

Ataxy and Sewing Machines.

In the *Union Médicale*, M. Octave Guelliot contributes a valuable paper on two cases of locomotor ataxy in women employed on sewing machines. In hysterical women, working at the sewing machine seems to be, in certain cases, the occasional cause of the appearance of locomotor ataxy. The symptoms commence in the lower limbs and progress upward. Shooting pains traverse the limbs from below upward. Improvement is noticed when the patient rests, and it may last a long time. Working at the machine by means of a treadle probably acts chiefly by the concussion, which is diffused throughout the spinal cord. Therefore, the continuous movement of the treadle is dangerous to the work-woman, and endeavors should be made to substitute some other motor for the foot-power.

Hypertrophy of the Prepuce.

The *Lancet* says that Dr. J. Jatrondaky has forwarded brief notes and two photographs of a very interesting case recently under his care. The patient, nine years of age, had from birth suffered from general hypertrophy of the penis, which was principally marked in the prepuce, which formed a firm, nodular mass projecting far beyond the glans penis. This he amputated, and obtained union by first intention with a very good result. The patient and his parents had good health, and there was no other malformation or disease, so that Dr. Jatrondaky is unable to regard it as a case of elephantiasis, and considers the affection simply hypertrophy of the prepuce.

Cæsarean Section.

The *British Medical Journal*, of March 4th, editorially says: The patient suffering from epithelioma of the cervix uteri complicating pregnancy, whose case Dr. Edis brought under the notice of the Fellows of the Obstetrical Society at the December meeting, was taken in labor at term, on a Saturday evening, in the Middlesex Hospital. On Sunday morning Mr. Henry Morris performed Cæsarean section. The operation was performed in the interests of both mother and child. On the following Wednesday both mother and child were progressing favorably.

The *Louisville Courier-Journal* says: "Washington scene; deep-voiced guzzler.—'Hi waiter! bring me three more schooners.' Awe-struck spectators whispering—'That must be the new Secretary of the Navy.'"

Special Reports.

NO. IV.—ADULTERATIONS (Continued from p. 362).

FLOUR.

In the Cincinnati *Medical News*, Dr. Ephraim Cutter, of New York, records the results of an examination of some food stuffs. The quantity taken of each specimen was enough to make a thin circular film, three-quarters of an inch in diameter, thoroughly moistened with water. Power, 200 diam. For a *standard*, the "*Lost Nation*" Wheat Meal was taken. This wheat has a very large and well developed grain, of great beauty. The wheat was simply ground up, without bolting.

There were found starch bundles, some of them perfectly preserved, having the beard, and about 300 gluten cells. It follows, then, that a flour, to be perfect, should present 300 gluten cells in the above amount. Then follows a long list of flours examined, from which will be selected those found to be good and satisfactory. The Arlington Wheat Meal, made at Arlington, Mass., is accorded a very high rank, Dr. Cutter saying, "Many examinations, conducted during a long interval of time, show this to be rich in gluten, and in the coats of tegument. It is what it claims to be—a meal made from the best winter white wheat the market affords. It comes next to the standard meal alluded to above." The "Entire Wheat Flour", made at Lockport, N. Y., comes in for a goodly share of commendation. Several of the prominent farinaceous foods for children were submitted to examination, and found wanting in the elements of nutrition claimed, some of them being even inferior in nutritive value to common flours. The following test for ergot in flour, formulated by Zinnia, has been improved by Jacobs. The suspected flour is repeatedly boiled with alcohol; it is then filtered, and a little cold alcohol, previously acidulated with sulphuric acid, is added. The presence of ergot will be demonstrated, in a few minutes, by the appearance of a beautiful rose color on the upper layer of fluid, from the intensity of which tint the amount of ergot may be judged. Dr. Charles Stuart (*National Board of Health Bulletin*) states that manufacturers of flour do not use alum for adulterating, but that bakers use it in making bread, to render it whiter. Flour is sometimes adulterated with soapstone, to detect which the *Mining and Scientific Press* recommends the following: Burn a sample of the suspected flour; an excess of ash will betray the cheat. Before considering any new articles, it will be well to get a definite idea of what is meant by adulteration. The *National Board of Health* thus defines adulteration:—

(*a*) *In the case of Drugs.*

1. If, when sold under or by a name recognized in the United States Pharmacopœia, it differs from the standard of strength, quality or purity laid down therein.

2. If, when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia or other standard work on materia medica, it differs materially from the standard of strength, quality or purity laid down in such work.

3. If its strength or purity falls below the professed standard under which it is sold.

(*b*) *In the case of Food or Drink.*

1. If any substance or substances has or have been mixed with it, so as to reduce, or lower, or injuriously affect its quality or strength.

2. If any inferior or cheaper substance or substances have been substituted, wholly or in part, for the article

3. If any valuable constituent of the article has been, wholly or in part, abstracted.

4. If it be an imitation of, or be sold under the name of, another article.

5. If it consist, wholly or in part, of a diseased, or decomposed, or putrid, or rotten, animal or vegetable substance, whether manufactured or not, or in the case of milk, if it is the product of a diseased animal.

6. If it be colored or coated, or polished, or powdered, whereby damage is concealed, or it is made to appear better than it really is, or of greater value.

7. If it contain any added poisonous ingredient, or any ingredient which may render such article injurious to the health of a person consuming it.

Sec. 10. The term "food," as used in this Act, shall include every article used for food or drink by man. The term "drug," as used in this Act, shall include all medicines for internal or external use.

The following is the law to prevent the adulteration of food and drugs, passed by the legislature of New York, and signed by the Governor, June 2d, 1881:—

Section 1. No person shall, within this State, manufacture, have, offer for sale, or sell, any article of food or drugs which is adulterated, within the meaning of this Act, and any person violating this provision shall be deemed guilty of a misdemeanor, and, upon conviction thereof, shall be punished by fine not exceeding fifty dollars for the first offence, and not exceeding one hundred dollars for each subsequent offence.

Sec. 2. The term "food," as used in this Act, shall include every article used for food or drink by man. The term "drug," as used in this Act, shall include all medicines for internal or external use.

Sec. 3. An article shall be deemed to be adulterated within the meaning of this Act:—

[In the case of drugs. (1) If, when sold under or by a name recognized in the United States Pharmacopœia, it differs from the stand-

ard of strength, quality or purity laid down therein. (2) If, when sold under or by a name not recognized in the United States Pharmacopœia, but which is found in some other pharmacopœia or other standard work on materia medica, it differs materially from the standard of strength, quality or purity laid down in such work. (3) If its strength or purity fall below the professed standard under which it is sold.]

[In the case of food or drink. (1) If any substance or substances has or have been mixed with it so as to reduce, or lower, or injuriously affect its quality or strength. (2) If any inferior or cheaper substance or substances have been substituted, wholly or in part, for the article. (3) If any valuable constituent of the article has been, wholly or in part, abstracted. (4) If it be an imitation of, or sold under the name of, another article. (5) If it consists, wholly or in part, of a deceased, or decomposed, or putrid, or rotten, animal or vegetable substance, whether manufactured or not, or in the case of milk, if it is the product of a diseased animal. (6) If it be colored, or coated, or polished, or powdered, whereby damage is concealed, or it is made to appear better than it really is, or of greater value. (7) If it contain any added poisonous ingredient, or any ingredient which may render such article injurious to the health of a person consuming it: Provided that the State Board of Health may, with the approval of the Governor, from time to time declare certain articles or preparations to be exempt from the provisions of this Act; and provided further, that the provisions of this Act shall not apply to mixtures or compounds recognized as ordinary articles of food, provided that the same are not injurious to health and that the articles are distinctly labeled as a mixture, stating the components of the mixture.]

Sec. 4. It shall be the duty of the State Board of Health to prepare and publish, from time to time, lists of the articles, mixtures, or compounds declared to be exempt from the provisions of this Act, in accordance with the preceding section. The State Board of Health shall also, from time to time, fix the limits of variability permissible in any article of food, or drug, or compound, the standard of which is not established by any national pharmacopœia.

Sec. 5. The State Board of Health shall take cognizance of the interests of the public health, as it relates to the sales of food and drugs, and the adulteration of the same, and make all necessary investigations and inquiries relating thereto. It shall also have the supervision of the appointment of public analysts and chemists, and upon its recommendation, whenever it shall deem any such officer incompetent, the appointment of any and every such officer shall be revoked and be held to be void and of no effect. Within thirty days after the passage of this Act the State Board of Health shall meet and adopt such measures as may seem necessary to facilitate the enforcement of this Act, and prepare rules and regulations with regard to the proper methods of collecting and examining articles of food or drugs, and for the appointment of the necessary inspectors and analysts; and the State Board of Health shall be authorized to expend, in addition to all sums already appropriated for said Board, an amount not exceeding ten thousand dollars, for the purpose of carrying out the provisions of this Act, and the sum of ten thousand dollars is hereby appropriated out of any money in the treasury not otherwise appropriated, for the purposes in this section provided.

Sec. 6. Every person selling, or offering or exposing any article of food or drug for sale, or delivering any article to purchasers, shall be bound to serve or supply any public analyst or other agent of the State or local board of health appointed under this Act, who shall apply to him for that purpose, and on his tendering the value of the same, with a sample sufficient for the purpose of analysis of any article which is included in this Act, and which is in the possession of the person selling, under a penalty not exceeding fifty dollars for a first offence, and one hundred dollars for a second and subsequent offences.

Sec. 7. Any violation of the provisions of this Act shall be treated and punished as a misdemeanor; and whoever shall impede, obstruct, hinder, or otherwise prevent any analyst, inspector, or prosecuting officer in the performance of his duty, shall be guilty of a misdemeanor, and shall be liable to indictment and punishment therefor.

Sec. 8. Any Act or parts of Acts inconsistent with the provisions of this Act are hereby repealed.

Sec. 9. All the regulations and declarations of the State Board of Health, made under this Act, from time to time, and promulgated, shall be printed in the statutes at large.

Sec. 10. This Act shall take effect at the expiration of ninety days after it shall become a law.

The work of analysis provided for by this bill is arranged under eleven heads and groupings, and allotted as follows:—

Animal Food. I. Milk, fresh and condensed. Assigned to Professor Chandler. II. Butter, dairy and artificial; cheese, lard, olive oil, and fruit essences. Assigned to Professor Caldwell, of Cornell University. III. Canned meats and animal foods; meats, fresh, smoked, salted, canned; extracts and essences of meat and fish; gelatine and isinglass. Assigned to Professor Chester, of Hamilton College.

Vegetable Food. IV. Cereals and the products and accessories of flour and bread foods. Assigned to E. G. Love, PH. D., of New York. V. Canned fruits and vegetables, pickles, preserves, spices, etc. Assigned to Professor Lattimore, of Rochester University. VI. Sugars, syrups, molasses, glucose, confectionery, honey, and soda-water syrups. Assigned to Dr. W. H. Pitt, Buffalo. VII. Tea, coffee, cocoa. Assigned to Professor Lattimore. VIII. Wines, beers, spirits, and cordials. Assigned to F. E. Engelhardt, PH. D., Syracuse.

Drugs. IX. Crude vegetable and animal drugs. Assigned to Frederick Hoffman, PH. D., New York. X. Pharmaceutical chemicals and their preparations. Assigned to Dr. Hoffman, XI. Organic preparations employed in medicines; cinchona, opium, etc., and their alkaloids; com-

mercial pills, coated and otherwise; ethers and essences. Assigned to Professor Caldwell.

The North Carolina Board of Health recently issued the following circular, which we glean from the North Carolina *Medical Journal*:—

To Householders and other persons interested in the prevention of the adulteration of food substances and medicines:—

The North Carolina Board, recognizing the widespread interest of the public in the rumored frequent adulteration of food substances and drugs, desires to give every facility to detect adulterations or quiet unfounded suspicions. While the Board does not share in the frequent public statements of the harmful adulteration and cheats in the food we eat, the liquids we drink, and the medicines we give it was deemed advisable to offer as many as desired it, up to the full capacity of the laboratory, analysis of suspected articles. The list of articles given below need not be the limit of the inquiry, but may serve to direct attention to the class of articles:—

FOOD SUBSTANCES.

Soda, saleratus, baking powder, cream of tartar, sugar, milk, butter, liquors, flour, etc., etc.

DRUGS.

Paregoric, laudanum, quinine, opium, and such articles as are usually sold for domestic use.

Upon application to the superintendent of health of your county, you can procure the necessary information. It is the intention of the Board to pursue the subject patiently, and upon these investigations to determine whether they will advise the State to enact laws upon the subject.

WATER.

The complete analysis of suspected water requires much chemical skill, but the more common impurities may be detected by simple tests. Among the most important impurities, the Boston *Journal of Chemistry* recognizes the *nitrates*, the presence of which is chiefly significant as showing that organic matter has been acted upon and may be present. The danger is not in the salts themselves, but in their source, which should, if possible, be detected. To examine water for nitrates, put a small quantity of it in a test tube; add an equal quantity of pure sulphuric acid, using care that the fluids shall not mix; to this add, carefully, a few drops of a saturated solution of sulphate of iron. The stratum where the two fluids meet will, if nitric acid be present, show a purple, afterward a brown color. If the nitric acid be in minute quantities, a reddish color will result. The presence of ammonia, if in excess, can be determined by treating the water with a small quantity of potassic hydrate. Ammonia, if present, will be liberated, and may be recognized by its odor, or by the white fumes of chloride of ammonium, when a glass rod wet with muriatic acid is passed over the mouth of the test tube. If chlorine is present in any form in water, it is evidence that sewage contamination in some form exists. The presence and amount of chlorine may be ascertained by the following simple method: Take 9 grains of nitrate of silver, chemically pure, and dissolve it in 200 units, (say cubic centimetres) of distilled water. One unit of the solution will represent $\frac{1}{100}$ of a grain of chlorine. Take a small measured quantity of water to be examined, and put it into a glass vessel more than large enough to hold it. Add to the water a small quantity of the solution; if chlorine be present, a white precipitate will result. Repeat the addition, after short intervals, until no precipitate results. The units of the solution used will determine the hundredth of a grain of chlorine present. If more than a grain of chlorine in a gallon be present, reject the water, unless it can be clearly determined that the excess does not come from sewage. The water should be slightly acidulated with nitric acid before the test is applied.

Heisch's sugar test for the presence of dangerous organic matter is at once simple and trustworthy. Place a quantity of the water to be examined in a clean glass-stoppered bottle; add a few grains of pure sugar, and expose to the light, in a window of a warm room. If the water becomes turbid, even after exposure for a week, reject; if it remains clear, it is safe.

(*To be Continued*).

Correspondence.

Compounding a Felony.

Ed. Med. and Surg. Reporter:—

Permit me to thank you, warmly, for the honest and manly words at the head of this correspondence, found in your able editorials upon the recent action of the New York State Medical Society. During a professional life of more than a third of a century, it has always seemed to me that to consult with homœopaths was to *compound a felony*. How can it be otherwise, in view of the teachings of science and of infinitesimals? To me, it has been one of the incomprehensibles of life that, in the light of these teachings, we should be censured, as we often are, for declining to meet, professionally, those whose views of medicine and disease differ so widely from our own. Let honesty be the standard, and none who know this divergence can, for a moment, think of such consultation. Why, then, offer a premium for dishonesty?

That the masses should not fully comprehend the distinction between the two schools I can readily understand, and easily pardon; but, for those who claim to comprehend it, or, for those whom we have a right to believe should, I have

no such consideration. A request to consult with such brings a conviction that the welfare of the sick is not alone the object sought. Choice in physicians or remedies cannot be questioned. The same may be said with reference to the practice of medicine; but, that regular medicine can consult with those whose medical shibboleth is so unlike its own, or, that it is open to censure for refusing to do so, is positively without reason.

That a body of scientific and honorable men, such as we have hitherto supposed the Society referred to, should attempt to force coalescence, is without precedence. That it can be done will be found impossible. So long as "a right and a wrong exists," and we have regard for the right, so long must we decline to meet, professionally, homœopathic physicians. Any deviation from this Hippocratic rule is professional apostasy. With homœopaths, personally, I have no quarrel. Among them are some of my best friends. For their medical assumptions, however, I have a most profound contempt; as I have for those among them who, under the guise of homœopathy, practice regular medicine.

Osage, Iowa, March 21,'82. S. B. CHASE, M.D.

Contagious Headache.

ED. MED. AND SURG. REPORTER:—

We must modify our ideas of contagion. Col. R. G. Ingersoll was asked by a religious defender of the orthodox faith, if he, Ingersoll, could have had the making of the universe, what better he could do than has been done. Says the Col.: "For one thing, I would have made good health contagious, instead of disease."

In a limited measure, good health is contagious to-day. Not contagious in the sense of subtle fomites multiplying in a period of incubation, but by a law of total transfer. The good health of one person is exchanged for the morbid state of another person. Headache is one of the maladies contagiously contracted. Two relatives intimately known to the writer have been repeatedly afflicted in that way.

One, Mrs. R., is a nervous person of a spare habit and light complexion. She has a young lady friend who has had hip disease, and is often suffering from impaired health, and is frequently afflicted with headache. These two have been more or less intimate companions. On one occasion the friend said to Mrs. R., "It does me so much good to visit you; if I have the headache, I notice I soon get well of it when I see you." Mrs. R. laughed, and answered, "I am always glad to see you, but I guess I contract your aches, for my headache begins when yours leaves." Mrs. R. observed that this phenomenon occurred many, many times during this acquaintance of three or four years. Mrs. R. relates another instance where she took a violent headache by rubbing the head of another young lady friend who was laboring under a severe attack of the malady.

The other case is that of Miss P., a person of spare habit, light complexion, blonde hair. While indulging in a carriage ride with her uncle and a lady friend, one summer's day, the lady friend remarked, "How pleasant; this ride does me good. I started with a fearful headache, but it is now nearly gone." Miss P. answered, "Yes, this is a pleasant ride, but I guess I have taken your headache, for my head pains me severely, though I was perfectly well when we started. I do not understand it." Miss P. relates a similar experience which happened to her in S. F. These contagious maladies, in both these patients, would pass off in a few hours, or after a night's rest.

But the most unique part of Miss P.'s susceptibility is to be stated. She has a lady neighbor whom she visits once a week, quite regularly. This friend is "queer," and is subject to visitations of peculiar psychological states. When a social visit happens between them during the existence of one of these peculiar mental states in her friend, Miss P. contracts a headache; sometimes severe, sometimes less so, but always a painful cephalalgia. The friend does not admit that she has headache, but she experiences a confused, unpleasant cerebral "sensation." Coincident with this cerebral sensation in the friend is the cephalalgia of Miss P. But differing from that of other cases, and differing from the incidents with Mrs. R.—where headache contracted by the one was a headache relieved in the other—the semi-head distress of the friend did not leave with the accession of cerebral pain of Miss P.

There is no *coincident* explanation for this matter; for the phenomena have been occurring once a week to once a month, now, for three years.

What explanation for *contagious headache* will the medical faculty offer?

A. S. HUDSON, M.D.

Stockton, Cal., March 17*th*, 1882.

Forced Suspension of Respiration.

ED. MED. AND SURG. REPORTER:—

Text books of physiology speak of some effect on the circulation, but I have not seen a therapeutic effect ascribed to a suspension of respiration.

Having suffered very often from coryza, I tried the suspension of respiration, and with marvelous results. For the last two or three years I have taken no medicine whatever for it. My experience warrants me in saying that in the incipiency of taking cold it is a sure therapeutic procedure. Indeed, I think it of benefit in all congestions, active and passive, to the head.

My plan is quite simple: upon a partial inspiration cease breathing for 30 to 60 seconds and repeat after several respirations, and so continue until the desired effect is produced.

Columbia, S. C. J. D. F. LEVER, M.D.

Luxation of the Unciform Bone.

ED. MED. AND SURG. REPORTER:—

A few weeks ago I was called to see a railroad brakeman who had fallen from a freight car. In falling he had struck his hand against the car. He was found to have a simple luxation of the unciform bone anteriorly. It lay just beneath the skin, and its process could be distinctly outlined. Reduction was effected by direct pressure on the

bone, while the borders of the hand were approximated.

But few writers recognize a simple dislocation of this bone, and it is said that there are no recorded cases. JAMES G. BUCHANAN, M.D.

Allegheny City, Pa.

NEWS AND MISCELLANY.

Pennsylvania State Medical Society.

The thirty-third annual session of the Medical Society of the State of Pennsylvania will be held at Titusville, May 10th, 11th, 12th, 1882. The officers for 1882 are as follows: President, Jacob L. Zeigler, M.D., Mount Joy. Vice Presidents, Joseph A. Reed, M.D., Dixmont; W. Roland, M.D., York; J. M. Houston, M.D., Chester; W. Murray Weidman, M.D., Reading. Permanent Secretary, Wm. B. Atkinson, M.D., Phila. Recording Secretary, G. Thickstun, M.D., Wattsburg. Corresponding Secretary, O. H. Allis, M.D., Phila. Treasurer, Benjamin Lee, M.D., Phila. Committee of Publication, Wm. B. Atkinson, M.D., Phila.; Benjamin Lee, M.D., Phila.; O. H. Allis, M.D., Phila.; Wm. Goodell, M.D., Phila.; J. G. Stetler, M.D., Phila.; James Tyson, M.D., Phila.; Isaac Kerlin, M.D., Delaware City. Judicial Council, for one year, J. L. Stewart, M.D., Erie; John H. Packard, M.D., Phila.; Wm. Anderson, M.D. For two years, Wm. Varian, M.D., Titusville; Thos. Lyon, M.D., Williamsport; R. B. Mowry, M.D., Allegheny. For three years, Traill Green, M.D., Easton; H. L. Orth, M.D., Harrisburg; J. L. Carpenter, M.D., Pottsville. Committee of Arrangements, Wm. Varian, M.D., *Chairman*, Geo. O. Moody, M.D., Theo. J. Young, M.D., J. P. Hassler, M.D., E. H. Dewey, M.D., G. M. Dille, M.D., David Best, M.D., George W. Barr, M.D., E. M. Farrelly, M.D., G. L. Clark, M.D., D. M. Calvin, M.D., J. L. Stewart, M.D.

The attention of members and delegates is called to the following rules of order:—

RULE I. ORDER OF BUSINESS.—The order of business laid down by the Committee of Arrangements shall, when adopted, be rigidly adhered to, unless suspended, according to rule IX. Any person not ready to respond when his name is called shall forfeit his position in favor of the next on the list.

RULE II. LENGTH OF TIME OF ADDRESSES, ETC.—The stated annual addresses shall not exceed, in their delivery, thirty minutes, and voluntary communications, reports, etc. shall not exceed twenty minutes.

RULE III. UNFINISHED BUSINESS.—Matters unavoidably postponed, forfeited privileges, discussion of papers, etc. shall come under unfinished business.

RULE IV. NEW BUSINESS.—All matters not upon the programme must come under new business.

RULE V. EXCHANGE OF POSITION ON PROGRAMME.—Members may exchange position upon the programme, the exchange to be announced at the reading of the first substitute paper, report, etc.; the Secretary being notified in writing, and the same noted upon the programme of the President.

RULE VI. REGULATING DISCUSSION.—No person shall be allowed to speak a second time during a discussion, until all desiring to speak shall have had an opportunity; no speaker shall be entitled to more than ten minutes, except the reader of the paper, report, etc, who shall be entitled to fifteen minutes in closing the discussion.

RULE VII. PUBLIC NOTICE OF STATE SOCIETY.—Notice of the meeting of the State Medical Society, together with the programme, shall be made at least one month previous to the annual meeting; such notice to be published in the medical journals designated by the Committee of Publication.

RULE VIII. TO BE ESPECIALLY OBSERVED BY THE COMMITTEE OF ARRANGEMENTS.—The terms UNFINISHED BUSINESS and NEW BUSINESS shall form the last items of the programme for each morning and afternoon session.

RULE IX. SUSPENSION OF RULES.—The above rules shall not be suspended, except for a definite purpose, a definite time, and by unanimous consent of the members present.

PROGRAMME.

WEDNESDAY, MAY 10TH, 10 O'CLOCK A.M.

Society called to order by the President, Dr. Jacob L. Zeigler, of Lancaster county. Prayer, Rev. Henry Purdon, D.D. Reading the List of Delegates, Dr. William B. Atkinson, Permanent Secretary. Address of Welcome, Dr. George O. Moody, of Titusville. Report of Committee of Arrangements. Introduction of Delegates from other Societies, and of Visitors not Delegates. Report of Delegates to other Societies. Report of Corresponding Secretary. Calling upon Delegations for Members of Nominating Committee. Unfinished Business. New Business. Adjournment.

WEDNESDAY, 2 O'CLOCK P.M.

Amendments to the Constitution. Dr. R. S. Sutton offers the following:—

SEC. 2, ART. III of the Constitution shall be so amended as to read as follows: "Every member of a County Medical Society in Pennsylvania shall, so long as he is in good standing, be a member of the State Medical Society, and a delegate to its Annual Sessions."

Address in Surgery, 2.30 P.M., Dr. H. L. Orth, of Harrisburg. Reading of Voluntary Papers in the following order: "Gheel," Dr. S. S. Schultz, of Danville. "The Oleates and Oleopalmates in Skin Diseases," Dr. John V. Shoemaker, of Philadelphia. "Medicine and Something More," Dr. Traill Green, of Easton. "Procidentia and its Relief; With a Case," Dr. E. E. Montgomery, of Philadelphia. Unfinished Business. New Business. Adjournment.

EVENING SESSION, IN THE PRESBYTERIAN CHURCH. 7 *o'clock*, P.M.

Annual Address by the President, Dr. Jacob L. Zeigler, of Mount Joy. Adjournment. Receptions by citizens at their homes.

THURSDAY, MAY 11TH.

Convene at 9 o'clock A.M. Prayer, Rev. J. Allan Maxwell. Announcement of Nominating Committee. Reports of County Medical Societies.

Report of Committee on Schedule of Subjects for Preliminary Examination of Students, Dr. O. H. Allis, Chairman, of Philadelphia. Reports of Secretaries of County Societies of the number of Students under tuition, and the number examined by the Medical Examiners. Report of Committee on Defective Hearing of Locomotive Engineers, Dr. L. Turnbull, Chairman. Report of Treasurer, Dr. Benj. Lee, of Philadelphia. Address in Mental Diseases, 10 A.M., Dr. C. K. Mills, of Philadelphia. Reading of Voluntary Papers in the following order: "Some Questions Relating to Tonsillotomy," Dr. W. H. Daly, of Pittsburg. "Abscess of the Orbit," Dr. J. A. Lippincott, Pittsburg. "Hæmophilia, or the Hemorrhagic Diathesis," Dr. Thos. D. Dunn, of Philadelphia. "A Comparative Study of the Action of Certain Mydriatic Alkaloids," Dr. E. J. Jackson, of West Chester. Adjournment.

THURSDAY, 2 O'CLOCK, P. M.

Report of Nominating Committee. Address in Hygiene, 2.30 P.M., Dr. W. F. Muhlenberg, of Reading. Reading of Voluntary Papers in the following order: "Subjective Traumatism of the Eye, Dr. Wm. T. Little, of Philadelphia. "Treatment of Membranous Croup, with Cases," Dr. Wm. B. Ulrich, Chester. "Medical Relation of Prevailing Adulterations," Dr. Henry Leffman, of Philadelphia. "Puerperal Malarial Fever," Dr. B. E. Mossman, of Greenville. Unfinished Business. New Business. Adjournment.

THURSDAY EVENING, MAY 11TH.

Promenade Concert and Collation at the Oil Exchange, 9 o'clock P.M.

FRIDAY, MAY 12TH.

Convene at 9 o'clock A.M. Prayer, Rev. F. H. Rowley. Address in Obstetrics, 9.30 A.M., Dr. R. S. Sutton, of Pittsburg. Reading of Voluntary Papers in the following order: "Herniotomy, with a few Cases," Dr. E. Griswold, of Sharon. "Excision of Cartilage in Nasal Occlusion Due to Deviated Septum," Dr. Jno. B. Roberts, of Phila. "Clinical Notes," Dr. J. H. Musser, of Phila. "A Case of Ovariotomy," Dr. W. Varian, of Titusville. Unfinished Business. New Business. Adjournment.

FRIDAY, 2 O'CLOCK, P.M.

Reading of Voluntary Papers in the following order: "Management of the Perineum During Labor," Dr. Frances N. Baker, of Media. "A Rare Case of Nervous Disease," Dr. J. L. Stewart, of Erie. "Some Facts in Vaccination," Dr. G. W. Barr, of Titusville. "Hæmaturia," Dr. William S. Roland, of York. Appointment of Committees. Unfinished Business. New Business. Adjournment.

There will be a supplementary announcement of some other papers to be read, which will be furnished to our readers when issued.

RAILROADS.—The Pennsylvania Railroad and its branches will issue excursion tickets at the rate of two cents a mile. All who desire to avail themselves of this should notify the Permanent Secretary, stating the number of excursion orders required, and the railroad over which the party must travel to the place of meeting.

Titusville is located in Crawford county. The Allegheny Valley and Dunkirk Railroads both enter the town, which contains a population of over 11,000.

American Medical Association.

The Secretary of the Surgical Section of the American Medical Association requests all gentlemen who are writing papers to be read before that section at its next meeting to notify him at least one month before the time of meeting. And also to give at the same time the titles of their papers and their probable length. By so doing the titles will be published in time for the members to be prepared for the proper discussion of the various subjects. And he suggests that all gentlemen taking part in the debates reduce their remarks to writing, so that the report may be more accurate and valuable as a mirror of present scientific thought. Communications should be addressed to Wm. A. Byrd, M.D., Sec., Surgical Section, American Medical Association, 407 Jersey street, Quincy, Illinois.

OBITUARY NOTICE.

THOMAS POTTS JAMES.

On February 22d, 1882, Thomas Potts James died suddenly, at Cambridge, Massachusetts, of paralysis. He was born at Radnor, Pennsylvania, September 1, 1803. He has held the following positions: Fellow of the American Academy of Arts and Sciences, Fellow of the American Association for the Advancement of Science, Member and some time Officer of the American Philosophical Society, Treasurer of the American Pomological Society for 27 years, Officer of the American Pharmaceutical Society, and also of The Philadelphia Drug Exchange; Professor of Botany to the Pennsylvania Horticultural Society, Member of the Boston Society of Natural History, Honorary Member of the Massachusetts Horticultural Society, and of other kindred Associations.

Until within a few hours of his death, Mr. James was working on a Manual of North American Mosses, which he, in connection with M. Leo Lesquereux, was preparing for the press, giving the result of the study of the past forty years.

MARRIAGES.

HAYNES—FELLOWS.—On March 14th, 1882, by Rev. H. L. Jones, at the residence of the bride's parents, John R. Haynes, M.D., of Philadelphia, and Miss Dora Fellows, of Wilkesbarre, Pennsylvania.

DEATHS.

HENRY—On Monday, March 13th, of scarlet fever, Paul Gerard, youngest child of Dr. E. P. and Josephine B. Henry: on Sunday, the 26th, Josephine B., wife of Dr. E. P Henry and daughter of the late Thomas D. Nancrede, and on Monday, the 27th, of scarlet fever, Frederic Nancrede, eldest child of Dr. E. P. and Josephine B. Henry, aged 11 years and 6 months.

LEON—On the 24th instant, Joseph M. Leon, M.D., aged 80 years.

MOORE—Suddenly, at Germantown, on Saturday morning, March 25th, Thomas Moore, M.D.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

PUERPERAL ECLAMPSIA.

BY L. S. MANNING, M.D.,
Of Manchester, Kentucky.

By way of preface I should say that the physician in this country is his own druggist and carries his supplies with him. What he does not have in the way of drugs or instruments he does without, since he can neither buy nor borrow for emergencies. Hence, the doctor, when he starts on a twenty-mile ride, has to select what he shall take and what he shall leave. To the patient it is far more important that he should take quinine than that he should take a thermometer; that he should take *veratrum viride*, rather than a sphygmograph. So when your country practitioner has made a selection of drugs, and crammed into his bags a few plasters, with a very few of the most common instruments, he has a load for his "one horse." These circumstances account for the omission of some important details in the histories following; and moreover, when at this terrible juncture the friends of the patient, in great anguish, are appealing to you for succor, if you do not lose your presence of mind, your attention will be wholly occupied with efforts of relief, rather than in the application of instruments of precision.

Case 1.—March 4th, 1874. Mrs. D., white, married, æt. 20, primipara. Saw her at 5 A.M. Has sore mouth and headache. Skin moist, pulse normal. Bowels and bladder just evacuated. Recurring pains at intervals of five minutes. Digital examination reveals the os uteri thin, dilating, dilatable, vertex presenting but not yet engaged in superior strait. 9 A.M. Very little advancement. Pains more frequent and stronger. Without warning, had a convulsion at 11.20 A.M., which lasted three minutes. After this administered Squibb's strong ether, by inhalation, but at 12 M. she had another convulsion. Ruptured membranes, used forcible dilatation, and pushed the ether, but not to the extent of complete anæsthesia. 2 P.M. Labor advancing; withheld ether, when she went into another convulsion. After this kept her under the partial influence of ether till the birth of a living male child, weighing nine pounds, at 3.30 P.M. Had used f℥ xij ether. Everything was arranged for the mother's comfort, but at 4 P.M. had another convulsion. Gave—

℞. Chloral, gr. xv
Potass. bromid., gr. xx,

in syrup, once in three hours. At 4.30 P.M. she lay moaning, skin hot, pulse 120. At 6 P.M. had another convulsion.

March 5th. No more convulsions. Patient could recollect none of the occurrences of the previous day. Mother and child doing well. Uninterrupted recovery.

Case 2.—April 5th, 1875. At 9 P.M. called to Mrs. W., married, multipara, æt. 24. Complains somewhat of frontal headache. Pains have been getting stronger and more frequent for some hours. Examination revealed os uteri dilating and dilatable. Had entered on second stage of labor, vertex presenting, first position. Three or four pains delivered a living female child with cord around its neck. Severed cord and passed the child to a nurse. In twenty min-

utes removed secundines entire. I should have stated that during third stage of labor gave fld. ext. ergot, ʒj, with brom. pot., grs. xxx. Applied binder, and everything was arranged for the mother's comfort. We were sitting around congratulating her upon her happy delivery, when, without any warning, she had one of those dreaded convulsions. When she began to breathe naturally again, administered chloroform by inhalation, to partial anæsthesia, whenever patient manifested restlessness, till 1 A.M., March 6th, when I gave her pulv. Doveri, grs. viij, which was vomited. At 4 A.M. the same was repeated and was retained. At 7 A.M. gave brom. pot., grs. xxx, with tr. verat. virid., gtt. vj, and repeated the same in four hours. 6 P.M. Has had several hours' quiet sleep. Recollects none of the occurrences of previous night after the convulsion.

April 7th. Mother and child doing well.

April 8th. Secretion of milk established. From this time on recovery was rapid and complete.

CASE 3.—May 7th, 1878, S. B., colored, unmarried, primipara, aged 19, very robust build; would weigh, perhaps, 185 pounds; attendants say she began staggering about and talking like a crazy person, twelve hours previous to my visit, 9 A.M. Had had a number of fits; none could tell how many. Was now comatose, tongue swollen and protruding, breathing laborious, frequent, stertorous; pulse 90 and small. Tied up the arms and opened a vein in each, at the elbow. Let the blood, which was of a very dark color, flow until it ceased spontaneously, when about ʒ xxx had been withdrawn. Found the pulse had improved. Attempted forcible dilatation of os uteri, but without success.

℞. Chloral, gr. x
Pot. brom., gr. xx,

in syrup every three hours. At 5 P.M. no more convulsions; breathing improved; tongue withdrawn; some feeble labor-pains, and labor had advanced to second stage; vertex presenting; fœtus evidently dead. If I had owned obstetric forceps, I would have delivered my patient at this time, but was forced to leave all to nature, only giving a cathartic to stimulate expulsive pains.

May 7th. During the past night she was delivered of a dead fœtus; still unconscious, and has evacuated bladder and rectum in bed, without warning. Ordered her to have ergot and quinine.

May 9th. Consciousness has returned, but recalls nothing of the events of the past three days. Complains of frontal headache, with great stiffness and soreness all over.

She made a rapid recovery.

CASE 4.—February 19th, 1880. F. W., single, white, primipara, robust and healthy. Had been complaining of headache and feeling badly for a day or two. Was taken with convulsions at 4 A.M., and I saw her at 2 P.M.; just passed through a convulsion. Tongue swollen and protruding, bleeding in places; breathing labored, frequent and stertorous; examination showed first stage of labor begun; os uteri thin, dilating and dilatable. Tied up both arms and punctured veins at elbow. The right arm bled to ʒ xx, the left refused to bleed.

℞. Brom. pot., gr. xxx
Morph. sulph., gr. ⅓,

every hour. Gave chloroform by inhalation, and attempted to turn and get hold of the feet, but without success. Chloroform was pushed whenever she manifested great restlessness. At 4.30 P.M. second stage of labor had been completed, and having no forceps with which to deliver the child, I made an incision in the vertex of the already dead fœtus, and inserting my finger, soon accomplished delivery.

I now found hour-glass contraction of the womb, but with a little time and considerable exertion delivered secundines entire; at the same time stimulating the uterus to contract by kneading. At 5.30 P.M. tongue withdrawn; breathing much improved; pulse soft and compressible.

℞. Calomel, gr. ij
Sulph. morph., gr. ¼,

every six hours.

February 20th. Consciousness returned during the night. She has no recollection of the occurrences of the previous day. Symptoms favorable.

February 25th. Recovered.

CASE 5.—November 28th, 1880. Called to see Mrs. M., æt. 28, white, married, the mother of four children, the youngest seven days old. In her confinement had been attended by a midwife, and nothing unusual was noticed, except the patient was despondent, and frequently spoke of dying. She also had persistent headache; had no dropsy, nor had received any injury. Forty-eight hours before I saw her all thought she was doing remarkably well, when suddenly she gave a loud scream, followed by another. She said her head had burst, that she was going to die, and implored her husband to take good care of the children. Shortly after this she had a terrible convulsion, requiring the strength of three men to hold her in bed, biting her tongue, and frothing at the mouth. She never regained conscious-

ness, and had convulsions, recurring at intervals of less than an hour, for the next eighteen hours. When seen by me she had had no convulsions for five or six hours; skin cold and clammy; breathing rapid and superficial; pulse almost imperceptible; eyes fixed and staring. In a few minutes death ended the scene. No *post-mortem*.

Case 6.—June 1st, 1881. Mrs. W., white, married, fourth pregnancy. Saw her at 7 A.M. Attendants said she had had two hard fits, about half an hour apart; that it still lacked two or three weeks of her term; that she had passed large quantities of urine the night before; that she had complained very much latterly of persistent frontal headache; that just before each fit she had vomited bile mixed with mucus and saliva. She now vomited again, and attendants warned me she would have a fit. In a few moments I saw her eyes become fixed, her face drawn strongly over the left shoulder. Then commenced one of those terrible convulsions seen only in puerperal eclampsia, with her face drawn strongly to the *left*. Convulsion lasted between three and four minutes, patient biting her tongue and frothing at the mouth; remaining comatose several minutes after convulsion ceased.

As this patient was not in robust health, I resolved to try the morphia treatment. I, therefore, dissolved sulph. morph., grs. ij, and gave at once, *per orem*. Upon examination I found feet and legs slightly œdematous, os uteri high up, *thin*, dilated to the size of half a dollar. Made strenuous efforts at further dilatation, with some success. Head presentation—head not large, and pelvis roomy. At 9 A.M. she began vomiting again, and, fearing another convulsion, I applied chloroform to her nose; but it was too late. She went off into another fearful convulsion, her head this time drawn strongly to the *right*. I now tied up her arm and bled to ℥ xx. I also gave hypodermic injection of one and one-half grains sulph. morph. into the cellular tissue, over deltoid muscle. This made her drowsy, and I made still further efforts at dilatation. At 11 A.M. her respirations numbered ten per minute, pupils contracted, pulse 80 and full. She made another effort at vomiting, followed by convulsion. I now had the temerity to dissolve two grains more of sulph. morph., and administer *per orem*. At 1 P.M. patient profoundly comatose, respirations eight per minute. Without premonition she had a violent convulsion. After this had ceased the outlook was gloomy, indeed. Respirations sighing, as if each one would be the last, and numbered only four per minute. By my attempts at dilatation the respirations improved slightly, and at the end of an hour's hard work succeeded in applying long forceps and delivering a living female child weighing seven pounds. Child seemed fully developed, was cyanotic, and respiration was established with some difficulty. The placenta being removed, the mother was put to bed. Respirations four per minute, and sighing. Kept up artificial respiration by elevating arms above the head and bringing them back again to the sides for some hours. Gave strong, black coffee, and stimulating doses of carb. ammon. with quinine.

June 2d, 8 A.M. Patient has just recovered consciousness; recollects nothing since first convulsion; respirations almost normal; pulse 60, full volume; complains of headache, and of being sore and stiff all over. The child lived but twelve hours.

June 3d. Patient continued to complain of her head for some weeks, and, aside from an occasional cathartic, she had

℞.	Potass. bromid.,	gr. xx
	Tr. hyoscyam.,	f ℥ ss
	Tr. nuc. vom.,	gtt. v,

in syrup, three times a day.

June 30th. Patient able to be about the house, though still feeble and complaining of her head. At this writing she enjoys her usual health.

I offer a few deductions of my own, the value of which each one may determine for himself:—

1st. The division of puerperal convulsions into three classes, as is done by some obstetricians, is entirely without foundation. Hysterical convulsions are hysteria; epileptic convulsions are epilepsy; apoplectic convulsions are apoplexy; while puerperal convulsions, or eclampsia, are *sui generis*, and without relief, tend to death.

2d. I consider Case 5 to be the course of puerperal eclampsia when unchecked by medical art. I have the first case to hear from that recovered without aid.

3d. In Case 6, I would have the reader note; (*a*) The head drawn first to one side and then the other, showing that the irritant is equally in both hemispheres of the brain; proving, as I believe, that these attacks are not apoplectic: (*b*) That no amount of morphia compatible with life will arrest all cases of puerperal eclampsia.

4th. Note that frontal headache is a prodrome in every case; and in every case where the fact was noted at all the os uteri was thin and stubborn in character, and the labor-pains were irritating and inefficient.

5th. The temperature was not taken in these cases, but I do not think there was great depart-

ure from the normal in a single case, unless it was lowered.

6th. If the urine had been tested after convulsions were established, doubtless albumen would have been found, as it is in all cases in which respiration is interfered with, and hæmatosis is imperfect.

7th. I would treat puerperal women with persistent headache by the exhibition of brom. pot. and nux vom. At inception of labor would give xx grain doses of chloral. After a convulsion I would bleed, deliver as rapidly as possible, give chloroform by inhalation at evidences of recurring convulsions, since they recur rhythmically, and the time of one seizure passed over, there is a lull, so to speak, until the next period of excitation. I would use chloroform so long as convulsions threatened, and use only moderate doses of opiates or other drugs.

PAPILLOMA OF THE RIGHT VOCAL CORD FOLLOWED BY ACUTE PHTHISIS.

Read before the Philadelphia Laryngological Society,

BY JOS. B. POTSDAMER, M.D.

Mary M. first came under my care in September, 1879, presenting the following family history: Her mother died of "consumption of the throat?" following exposure to wet and cold. Two brothers died of scarlet fever. A brother and sister are living, in ordinary health. The sister has a goitre.

Her history is as follows: When four years old, she had an attack of scarlet fever with sore throat. Every following winter until her fifteenth year she suffered from an ulceration of the throat, which was never burnt, with the exception of when she had scarlet fever. She makes a statement that "it was swabbed at that time with some black stuff." From the symptoms, such as confinement to bed in a sitting posture, attended with fever, we would come to the conclusion that the recurring attacks of sore throat were severe. Besides, the patient was only able to swallow liquids, which caused severe pain in the sub-maxillary region.

When about fifteen years old, she used for her sore throat twenty drops of spirits of turpentine in gum arabic water, three times a day, for two days, when she was caught in a rain and was drenched. There or four hours afterwards she lost her voice, but partially recovered it the next day. For the dysphonia she consulted a physician, who burnt her throat, which relieved the attending pain, but not the hoarseness. A series of quack remedies followed. In the spring of 1875 she went to the Northern Dispensary, where she was told she would have to undergo an operation. She was examined with laryngoscopic mirrors. From here she went to the Brown Street College. Here a homœopathic physician gave her some powders without affording any relief. In the summer of this year she tried Case's inhaler.

In September, 1879, she came to the throat department of the Jefferson College Hospital. At this time she was nineteen years old, 4 ft. 8 inches high, and weighed 95 lbs.; general health good. Here she was examined by Dr. Isaac Barton and myself, but we were unable to obtain a view of the interior of the larynx, owing to the fact that the epiglottis was depressed. We then referred her to Dr. J. Solis Cohen, who also failed in obtaining a view of the larynx. He ordered that we should endeavor to draw the epiglottis up permanently, by raising it by means of the laryngeal forceps every other day. This treatment was diligently pursued for about a month without raising the epiglottis sufficiently to enable us to obtain a view of the interior. Shortly after this, Dr. Cohen, while examining the patient, announced that he had at last been enabled to see the vocal cords, and that there was a papular growth on the right one. This was the only time that a view of the interior of the larynx was ever obtained. In October of this year she called my attention to an enlargement of the thyroid gland, which disappeared completely under the local use of the tincture of iodine.

During December, the patient visited Dr. Cohen. While at his office one day, she had a slight hemorrhage, attended with a suffocative spasm. At this time she had occasional attacks of these spasms, for which the Doctor ordered nitrite of amyl.

On the 3d of January, 1880, I was called in attendance at her house, and found the patient suffering from marked dyspnœa. It was with the greatest difficulty that she could breathe. The respirations were hurried, short, and gasping. The pulse was over 120. This attack lasted thirty-six hours, was relieved by nitrite of amyl and large doses of bromide of potassium. The attack resembled the suffocative spasm of croup. The patient was unable to lie down; at times she grasped her throat, as if to relieve herself of a foreign body. At intervals during the attack the respirations were natural.

Taking all the circumstances of the case into consideration, I put her upon the following treatment: Tincture of the chloride of iron, cod-

liver oil, and the compound syrup of the hypophosphites. The physical signs of the chest at this time, about January 15th, 1880, revealed somewhat rough vesicular breathing, with clear percussion sounds. The patient improved during the spring and discontinued her visits in the early summer. About April of this year she called my attention to the fact that she missed her menstrual period. Thinking this one of the early symptoms of beginning phthisis, I told her not to worry, but wait a few months, and perhaps the periods would return of their own accord. The treatment ordered at the beginning of the year was not given with the idea that the patient was suffering from any lung trouble, but, considering her weak condition and the previous history, with the idea of preventing it.

On October 14th of that year she came to my office to consult me in regard to a cough. She told me that since she last saw me she enjoyed excellent health. On physical examination I found she was suffering from an ordinary attack of bronchitis, for which I gave her muriate of ammonia, and she was well in a few days. At this visit she told me she was married, and engaged me to attend her in confinement. I now saw her occasionally, examining the larynx and lungs. The former I was never able to see; the latter exhibited nothing abnormal. On December 28th I was called, about 8 o'clock in the evening, and was told she was in labor. On physical examination, I found she was suffering from dilating pains, which were infrequent, and continued so until the evening of January 4th, 1881, when, finding the os uteri dilated to the size of half a dollar, I applied a large belladonna ointment to it. This caused the os to dilate rapidly and the child was born a few hours later. After the ordinary period of "lying-in," the mother was able to go about as usual. Having a bountiful supply of milk, she nursed the child at the breast. I visited her occasionally, examining the lungs at times, but never detecting any change.

Toward the end of July she complained of pain in the left ear, accompanied by a purulent discharge. She went to the country before I had an opportunity to examine into the cause. Owing to the fact that the baby had ileo-colitis, she returned to the city on the 5th of August. I then examined the ear and found a perforation of the membrana tympani. The chest at this time revealed the following physical signs: right side, marked bronchial breathing, both anteriorly and posteriorly, with crackling at the apex. Marked dullness on percussion over the whole of this side of the chest. Left side: beginning bronchial breathing over all this side, more marked toward the apex; percussion sounds somewhat dull. From this time on the case rapidly progressed to a fatal issue. About the middle of October the patient occasionally had attacks of suffocation somewhat similar to those previously described. Toward the latter part of this month the right ear became affected in the same way as the left one. For a week prior to death the patient was troubled with a persistent diarrhœa. During the last month of life the pulse varied from 120 to 140 beats per minute; the respirations from 48 to 60 per minute; temperature from 99° to 100.5°. This lasted until November 11th, when she died. It was impossible to obtain a post-mortem examination.

Although she nursed her child up to within six weeks of her death, it was against my direct instructions. I insisted, early in the summer, that she should wean it, but she would not listen, and it was only when she became confined to her bed that she did so. The child, a boy, is at this time apparently healthy.

The patient always attributed the dysphonia to the use of the turpentine. Considering the history of exposure to wet and cold, followed by aphonia, I concluded that the origin of the larynx trouble was an acute laryngitis which the patient suffered from at that time. The failure of the inflamed larynx to return to its natural state is due partly to improper treatment. Still, owing to the tubercular dyscrasia, with the best of treatment I doubt whether the larynx could have been restored to its normal condition. I base this opinion upon the fact that cases of subacute and chronic laryngitis in patients with a tubercular tendency seldom recover entirely; but eventually tubercle is found in the lungs, and after a period of three or more years the individual falls a victim to the disease. Two cases bearing out this statement have been before the Society, one in the spring and the other in the fall of last year.

The laryngitis becoming chronic gave rise to the papillomatous growth. That this is not of infrequent occurrence, is a fact supported by some of the best authorities.

The statement of Dr. C., of the Northern Dispensary, in the spring of 1875, "that the case would require an operation," would indicate that he obtained a view of the interior of the larynx and saw a growth there.

The laryngeal symptoms of the case in question did not materially alter during the three years that the patient was under my care, except

that her voice was stronger in summer than in winter. During the last two or three weeks of the patient's life her voice was very weak, which I attributed to the extreme exhaustion, and not to any change in the tissues of the larynx.

The perforations of the tympanic membranes were due to the deposit of tubercle in them.

Whether this was a case of pure tuberculosis of the larynx, preceding the deposit of tubercle in the lungs, or whether it was a case of chronic laryngitis with a papillomatous growth on the right cord, followed by pulmonary phthisis, is a question which I am not ready to answer, owing to the fact of being unable to make satisfactory laryngoscopic examinations, and to the absence of a necropsy. If the former, it goes far to prove two mooted points, to wit: 1st. That the deposit of tubercle in the larynx may and does, at times, precede its deposit in the lungs. 2d. That cases of primary tuberculosis of the larynx may live longer than three years from the onset of the disease.

Hughes Bennett's article in Reynolds' System of Medicine, Vol. II, page 119, "On the Causes of Phthisis," says: "As a general conclusion, we hold to the belief that the great cause of tubercle is weakness of constitution, or diminished vital power, however produced."

This explains why my patient became a victim of pulmonary disease. She being a girl in delicate health, with laryngeal disease, going through life without a change either for the better or worse. She marries, becomes pregnant, and has a child. This child, notwithstanding instructions to the contrary, she nurses at the breast until unable to do so any longer. What is the result? The extra drain upon her system is more than her nature can withstand, and the fuel which was ready to be ignited suddenly takes fire and rapidly consumes the victim.

IMPACTED CERUMEN; SOME OF ITS CAUSES AND TREATMENT.

BY DR. GEORGE F. SOUWERS,
Of Philadelphia.

If there is one thing more than another the treatment of which the general practitioner dreads, and upon which, in our so-called great medical schools, either he or the student, owing to the lack of lectures and demonstrations, can obtain little or no information about, it is the ear and its diseases; and while we confess that the subject does not permit of much brilliancy in manipulations, nor of apparently startling results, yet we must admit that in dealing with a man's hearing we have almost as important a factor to dispose of as when his sight, locomotion, and speech are the issues involved. Aside from actual structural disease, by which we mean the involvement of the essential portions of the auditory apparatus and the nerve of audition, we find that there is no more common cause of deafness in all its modifications, from inability to hear slight noises and sounds to absolute loss of hearing, than the impaction of masses, either moist or dry, of cerumen; further, there is hardly any agency which can be productive of more irreparable injury, when allowed to remain undisturbed in situ, than this substance; for while it is a natural product of the canal in which it is found, and while a certain amount of it is essential to the well being of the ear, yet it is one of those blessings which, when enjoyed to too great an extent, results in a curse. In considering the disorder under discussion it may be well to place our remarks under certain general heads, such as the cause, production and varieties of impaction, its relationship to aural eczema, the symptoms, general and special, by which the complaint may be characterized, the best plans of treatment, etc., etc. And first, as to the cause of the disorder; at this season of the year we have in profuse perspiration and bathing the two most common causes of impaction, the mechanism being as follows: a small piece of cerumen is lying loosely in the auditory meatus; a drop of perspiration, or in bathing, a little water, finds its way into the canal and carries along with it the fragment, until its further progress is prevented by its coming in contact with the membrana tympani, against which it lodges. The victim of the accident does not at the moment particularly notice what has taken place, or if he does he simply supposes that a few drops of water have "gotten into his ear," as he expresses it, and that they will shortly work their way out. The fact transpires, however, that this desirable consummation does not take place, and after a time a certain sense of uneasiness and fullness of the meatus, and difficulty of hearing, make themselves manifest. As a means of relieving the condition, the patient instinctively inclines his head to the side affected, and goes through a series of jumping gymnastics, in the hope of dislodging the water. It may now take place that a gush of warm water escapes from the meatus, which, however, the patient finds does not altogether relieve him of his uneasy sensations. Instead of a cessation of his troubles, he now begins to experience a series of noises in the head and ears, which are as various as there are sounds under heaven,

the more common being those resembling the ringing of bells, the whistle of escaping steam, the roar of sea-shells, etc. Associated with this condition there may or may not be more or less pain, which will vary in character from the pricking of needles and pins to merely a sense of pressure, or the pain may even be sharp, shooting, and neuralgic in character, being felt over the supra-orbital, temporal, and posterior auricular regions.

The state above described may be, for convenience sake, styled the acute condition or stage of impaction; and while, of course, the picture may be drawn a little more vividly than is generally witnessed by the physician, yet it is a true picture. He does not see it often, for the reason that the case has generally passed into the second stage of the disease before it comes under his notice, or into that condition in which the acute symptoms having been borne by the patient, and having subsided, may better be classified as a chronic condition, in which impaction proceeds gradually, layer after layer of cerumen being deposited, and, in consequence, an increasing pressure made upon the drum-head.

Now, of course, a different and yet the same series of symptoms will take place ere the third stage of the trouble is reached. But before considering these new manifestations and the third stage, let us review a new agency in the production of the impaction. It is an old saying that cleanliness is next to godliness; we would paraphrase this axiom somewhat by adding to it that too much cleanliness is not unfrequently next to deafness. There be those who labor under the impression that to secure clean ears it is essential that the meatus be daily scoured out by copious drenching of soap and water, that it is necessary that a corner of a towel shall be twisted into something of a probe shape, and that this, being smeared over with Castile or other soap, shall be passed deeply and with a rotary motion into the ear. Others, again, employ bodkins and hair-pins in order to dig out the wax, whereas, in many instances, they only succeed in pushing a large proportion of it further in. It is not an unusual experience among those who have the opportunity of examining a large number of ears, to find the meatus occluded by a mixture of soap and cerumen, the former having been introduced as above noted, the rotary motion employed serving still further to lodge the soap in position and to push any loose fragments of cerumen further back into the canal. There seems to be set up, under the irritation of the alkalies in the soap, a condition of chronic aural eczema, which, in fact, has been so commonly noted in the aural clinic of Jefferson Medical College Hospital, by Dr. Laurence Turnbull and his chief assistant, Dr. Chas. S. Turnbull, to whom I am indebted for favors in the production of this paper, that the trouble is diagnosed and docketed as "soap eczema," into the modifications of which complaint we shall enter later. I have the notes of a case in which, mixed with the impacted cerumen were fragments of slate pencil which the boy admitted having introduced. There was present a state of acute eczema, the meatus being red and inflamed; in this case the pain resembled that produced by the pricking of needles and pins.*

We come back, now, to some of the symptoms of the stage of chronic impaction, and we find the patient complaining of loss of hearing, noises in the head, *itching of the aural canal*, neuralgias, indistinct tinnitus, which he refers to various parts of the head, troubles due to involvement of the sympathetic nerve, through the branches supplying the ear; at times some slight discharge. His condition may be better and worse at different times; there may be, at times, intense lancinating pains in the ear, or a neuralgic condition of the whole corresponding side of the face, referable at times to neuralgia of the teeth, and a variety of such symptoms. On testing the hearing by the watch, it is found decidedly deficient, though the sound of a tuning-fork struck and held in the air may readily be recognized, thus differentiating the trouble from catarrhal conditions. It is a curious fact, however, that in some of these cases of chronic impaction there is present no tinnitus, pain, nor discharge, the only symptom being gradual and persistent loss of hearing. Now the patient is apt to charge the condition upon having been repeatedly the subject of colds, and while we admit this statement in coming to a diagnosis, we must also remember that the condition is very apt to be the symptom of some local skin disease, more especially eczema in one of its four most common forms, and that when the impaction is due to disease of the external meatus, the color of the impacted cerumen is changed from the rusty red of a simple impaction of healthy cerumen, to any shade between rusty red and jet black, the exfoliation in cases of eczema being incorporated intimately with the cerumen. In those in whom malaria has obtained a seat, especially if they be the victims rather of the dumb than the frank variety of the disease, the indistinct feeling of numbness which is at times present in those suf-

* Notes Case 1011, Jefferson Medical College Aural Clinic, 1881.

fering under impaction of cerumen, affecting more especially the temporal and lateral facial regions, may lead to their being treated only for the malarial condition, the real cause of the trouble being entirely overlooked, and so, of course, not treated. I do not think that I am alone in having seen cases whose only symptom of malaria was a persistent, or at times recurrent, tinnitus and numbness, the trouble rapidly yielding to an anti-malarial plan of treatment. Now, there are cases with similar symptoms, in whom a close examination alone will reveal the exciting cause. As a cause of chronic impaction, the shape of the ear must be taken into account. In old women who wear caps with strings fitting down back of the ears, so as, in a manner, to jam the posterior walls of the meatus externus forward, as it were, thus narrowing the canal and bringing the walls in abnormally close apposition, thus deepening, while, at the same time, more or less occluding the channel through which the secretion should normally find free exit, impaction is a very common event. The concha being thus artificially forced forward results in the production of the state known as "box ears." Of course, such a mechanical factor would have to be considered when it came to the question of treating such a case.

In these cases of chronic impaction, whether in the second or third stage, which last we have yet to consider, and in which they are particularly marked, there may be many sympathetic symptoms, the irritation being transmitted through the ganglia of the sympathetic in this region, indistinct headaches, troubles in vision, etc., being very common, these disappearing when the cause of the disorder is removed. In some cases the patient, thinking to provide a remedy for what he supposes is an impending abscessed condition, from the symptoms present at times, applies a poultice. This application is occasionally followed by a more or less abundant serous discharge, especially in eczematous conditions.

After remaining in the condition which we have denominated the second stage of impaction, there gradually begins to take place a crystallization of the constituents of the first deposited layers of cerumen; the crystals of cholesterine shoot out and interdigitate, forming a whitish-gray pellicle or mass, which is not visible through the speculum until the more recent and still semi-solid deposits of cerumen have been removed. It is now that the great destructive agency of impacted cerumen is made evident. The constant pressure of the sharp crystals against the delicate membrana tympani eventually results in an irritation and consequent inflammation of that membrane, which, unless promptly checked by the removal of the exciting cause, results finally in its ulceration and total destruction. The mischief, however, does not stop at this point, but may go on to a true otitis media, the essential bones of audition become involved, and the ear, as an acoustic instrument, is rendered entirely worthless. Lucky indeed is the patient if the case does not go on, by reason of the involvement of the temporal bone and the production of meningitis, to a fatal termination. In examining an ear in which the pressure of the stage of crystallization of cholesterine is suspected it is necessary to employ the head mirror, as both hands should be entirely free, in order to make the necessary manipulations for the removal of the mass. In those cases where ulceration has not yet commenced the drum-head will be found more or less thickened, opaque, and sunken, and the adjacent integument of the meatus more or less swollen and inflamed, presenting, at points, certain florid granulations, the passage being extremely sensitive, not, at times, even permitting of the passage of the speculum. These granulations and the sensitiveness may not be discoverable till after the removal of the masses of desquamated epithelium which frequently occlude, more or less, the calibre of the meatus. We have said that the primary cause of impaction may be an eczematous state of the meatus auditorius externus, and the question may be presented for consideration as to what extent the eczema may proceed; it may be laid down almost as a rule, that a case commencing as primary desquamative eczema will pass progressively, if untreated, through all the stages ordinarily assumed by that disease. In the first stage there is present simply a scaly desquamative condition of the skin, accompanied by more or less itching and irritation, or sometimes there being no further inconvenience than the mere scaling. The disease is now in a state to be readily and promptly cured, the removal of the exciting causes alone, frequently, being all that is required; the chief exciting causes may be laid down as too frequent and too copious washing of the ears, especially when soaps of different kinds are freely employed; it matters not whether the finest Castile or the commonest brown soap is used, the results are the same. If allowed to proceed on its way uninterrupted, the disease soon involves the true skin or derm in its ravages; this step in its progress being manifested by the presence and discharge of a more or less copious serous secretion; from this condition the third stage, of

ulceration, is soon evolved, terminating frequently, after prolonged suffering and inconvenience, in a hypertrophic condition of the integument of the meatus. As to the treatment of these conditions we shall speak later, in summing up the method of cure in all the different forms of impaction. In taking the history of a number of cases of impactions of cerumen from different causes, one's attention is particularly drawn to the fact of the involvement of the throat and fauces in the difficulty, as well as of the mucous membrane of the nasal passages.

In looking over a record of cases treated at the aural clinic of the Jefferson College Hospital, service of Dr. Turnbull, who kindly placed the books at my disposal in preparing this paper, entries like the following are, *in part*, the rule, rather than exception: M. G., employed in spice mill; has no pain, tinnitus or discharge; hearing distance normal, or nearly so, in right ear; left meatus filled with desquamations; membrana tympani, left ear, thick and opaque; *nasal passages inflamed; chronic pharyngitis and enlarged tonsils;* the hearing impaired for four years past.

Again, Case No. 1015. Cannot hear watch on contact; the membrana tympani thick and sunken; *throat and tonsils swollen;* impaction of cerumen present, the meatus being in an eczematous, scaly condition; has used palm soap freely every day. In the case of J. O. the same history comes again to the fore: mucous membrane of the nasal passage slightly thickened; that of the throat in like condition, and tonsils enlarged; and so it is with numbers of others; so that it would be well, in all cases of impaction, for the physician to go a step beyond the state actually complained of, and to study the condition of the throat; and, in fact, the rule may be as well applied *vice versa*, in obstinate chronic pharyngeal inflammations.

The question of treatment of these different conditions may now appropriately be considered. In those cases where we have to deal with a simple uncomplicated condition of impaction, lukewarm water and a syringe may be all that will be required to restore the ear to a normal and healthy condition. Where, however, impaction has passed beyond such a simple means for its removal, medicinal agents must be called into requisition. The simplest remedy, then, is glycerine, either alone or in combination with a little water; the patient being placed with the head reclining toward the opposite side to that being treated, a few drops of glycerine are dropped into the meatus; having been allowed to remain in situ for some minutes, the ear should be washed out with a mixture of glycerine and water, and then thoroughly dried. These applications should not be made more than twice in the twenty-four hours, under any circumstances, for, if too often repeated, more harm than good may result. If, however, the means considered fail to afford relief, we have in borax a very efficient agent by which to accomplish the end desired, namely, such a degree of solution of the cerumen as will admit of its ready removal by the syringe. A very good formula for the employment of this drug is as follows:—

℞. Sodii bromid. pulv., ℥j
Glycerinæ
Aquæ, āā ℥ij. M
Sig.—Warm, and drop into the ear.

When the impaction consists of a crystalline mass, which, by ulceration, has destroyed the membrana tympani, and forced itself into the middle ear; or even when external to the membrane, it is almost useless to employ the syringe alone; the use of a long, delicately tapering forceps is necessary for the removal of the mass, care, of course, being taken not to roughly handle the parts that are already in a state of irritation. A solution of alum may then be applied twice a day, if the indications point to the employment of astringents. If the fauces, etc., require it, they should be treated systemically as well as locally, for in many cases the patient presents an anæmic state of the system. As a gargle he may employ chlorate of potash and muriate of ammonia. If, now, eczema is the agent at work producing the mischief, another plan of treatment must be pursued. The first and grand law is "absolute prohibition of the use of water, or of water and soap, for the purpose of cleansing the ears." This is a *sine qua non* for the success of whatever else may be done. In those cases where the eczema has simply progressed as far as the first stage, an ointment of the yellow oxide of mercury, made of the strength of from one to two grains of the oxide to the drachm of cosmoline, and applied thrice a day, not only to the meatus itself, but also to the membrana tympani, is very useful. If an ulcerative condition is present the nitrate of silver is the remedy *par excellence*. If, however, the hypertrophic stage of the disorder has been reached there is no better application than that of the ol. cad., by means of a camel's hair pencil. If the patient insists on cleaning his ears out, let him use the end of a dry towel upon which a little cosmoline has been placed, taking care not to force it far back into the meatus; but it would be far better if he did nothing in the

matter, but allowed only an experienced hand to conduct his case to a successful termination.

AN EXTRAORDINARY CASE OF MORPHIA POISONING.

BY H. PRAEGER, M.D.,

Of Bethlehem, Pa.,

Ex-Senior Physician and Surgeon to St. Luke's Hospital.

G. B. L., about 50 years of age, of South Bethlehem, Pa., on the morning of December 15th, 1880, complained of a sick or nervous headache, a not unusual thing with him. He took a dose of paregoric, but the pain did not diminish. A little later he took a pill of ¼ grain morphia; shortly after repeated the dose till he had taken three or four, apparently without any relief. He then sent for a physician of this place, who on his arrival administered a hypodermic injection of morphia. After an hour or so had elapsed, and no relief was felt, recourse was had to some more pills of morphia. After an hour or so, feeling no relief, he again sent for the Doctor, who administered another hypodermic injection of morphia; this was now about seven P.M. I am not informed as to the quantity of the drug the patient took. At 8.45 I was telephoned by the patient's sister, Miss M. L., who urgently requested my services, stating, at the same time, she believed her brother was dying, and she thought it was from overdoses of morphia. Aware of the fact that death in opium narcosis chiefly occurs through failure in the respiratory function and the circulation, I thought at once of atropia, it being, in my estimation, the most reliable, and perhaps the only agent which exerts a decidedly stimulating effect upon the respiratory centres and cardiac inhibitory centres, and providing myself with a hypodermic syringe and a solution of atropia, I hastened to the bedside of the patient. I was with him within seven minutes of the call.

On scrutinizing his condition, and raising his eyelids, I perceived his pupils to be contracted to the size of a small pin's head, and totally insensible. Coma profound, deglutition entirely suspended; countenance deeply cyanosed; eyes closed; respirations three per minute and stertorous; pulse small, feeble and irregular. The muscles of the limbs and trunk were in a state of relaxation. I immediately administered a hypodermic injection of $\frac{1}{24}$ gr. atropia, with a view of stimulating the cerebro-spinal axis, and thereby exciting the action upon the vaso-motor nerves; moreover, to strengthen cardiac contractions, and thereby increase arterial pressure, which in opium narcosis is very much diminished, through paralysis of the vagus. While waiting twenty minutes, I applied, in the meantime, sinapisms to the præcordial region, with a view of stimulating the excito-motor ganglionic cells of the heart, and to the calves, with a view of stimulating the peripheral vaso-motor nerves. At the end of this time I gave another hypodermic injection of $\frac{1}{48}$ gr. of atropia. At this moment the family physician arrived; the patient's respiration being then four per minute and the cyanosed condition somewhat abated.

I stated to the Doctor that, in my opinion, the best treatment would be the continuance of the atropia, with the addition of caffein and the electric battery; to which he replied, "well, if that is the best thing to do, let us keep on." Upon this I hurried to my office, quite near, to procure my battery and the solution of caffein. During my absence, and while preparing the battery for action, the doctor administered to patient two injections, one of $\frac{1}{48}$ gr. atropia and one of 2 grs. caffein. When ready, I applied one electrode to the neck, while the other I moved along the margins of the ribs, so as to influence the diaphragm, and perhaps the ganglionic nerves. Inquiring if the patient had false teeth, I at the same time pressed down the chin, to examine, and found that the tongue had fallen back into the pharynx, from relaxation of its muscles, due to narcotism. I immediately grasped the organ and drew it forward, holding it in its new position; at once the stertor ceased, the breathing became less laborious and more natural, the respirations being then about 4½ per minute. The hypodermic injections were continued until about 11 o'clock; the tongue being kept forward; the respirations increasing at the rate of about one per hour, and being at this time about six per minute.

At this time the physician, in the presence of the patient's family and friends, exclaimed, "Dr. Praeger, I don't think this is a case of morphia poisoning." Why, Doctor, what else could it be? To which he replied, "Well, well, I don't think it is a case of morphia poisoning." I then said, Doctor, it surely is not cerebral apoplexy, for, as you see, there is no throbbing of the carotids, the pupils are contracted and the eyelids closed; nor is it asphyxia, as you see there is no swelling of the veins of the head and neck, eyes are not bloodshot, nor do they protrude from their sockets; nor is it uræmia. "Well, I could not say, but I don't think it is morphia poisoning." Under this condition of disagreement, the family thought it necessary to call in a third physician; a telegraphic

message was sent to Dr. S. W. Gross, narrating the facts of the case; an answer was received stating that the atropia treatment, etc., was correct. Nevertheless, a second telegram was sent, requesting his immediate presence. An express train was at once ordered, at Ninth and Green streets, Philadelphia, and by 1.30 A.M. Dr. Gross was at the patient's bedside. While viewing the case, several members of the family anxiously asked his opinion, to which he said, "It is a case of morphia poisoning." He then turned to me and asked what treatment I had pursued. I told him. He then said to all that were present, "All that can be done has been done." On seeing the gradual amelioration of his general condition continue, nothing more was suggested nor done, except as regards the tongue of the patient, which it was still found necessary to hold out, and which was held until about 9 o'clock A.M. I kept at the patient's bedside and closely watched for any untoward symptoms. At about 7 o'clock A.M. his respirations were 12 per minute; at this time I made a vigorous effort to rouse him. I shook and pinched him, and shouted loudly in his ears, at which he slightly raised his eyelids, and again relapsed into an apparent state of coma. At the end of half an hour or so I made another attempt to rouse him, but without avail; half an hour later he opened his eyes and made an effort to speak. I persisted in my attempts to keep him awake, and by continually shaking him, and hallooing loudly into his ear, he finally raised himself up in bed. His cerebral symptoms gradually subsided from this moment. There was now headache, nausea, and vomiting; his tongue was necessarily much swollen, tender, and painful, undoubtedly due to the constant pressure and irritation caused by the holding of it with the fingers, and presented features not unlike that of glossitis; these conditions lasted several days, during which time, at the request of the family, I continued my visits.

Hospital Reports.

WESTERN PENNSYLVANIA HOSPITAL, PITTSBURGH, PA.

SERVICE OF J. B. MURDOCH, M.D.

Reported by JOHN J. BUCHANAN, M.D., Resident.

Sarcoma of Lower Jaw; Removal; Recovery, with Recurrence.

Mary H., widow, aged 35, was admitted to the house, January 5th, 1882, with an enormous enlargement of the left side of the lower jaw. She stated that the trouble had commenced six months before, by a swelling the size of a pea on the alveolar border of the lower jaw. This she attributed to irritation by a broken molar tooth in the upper jaw. Since that time the swelling had progressively increased. At the time of her admission the growth extended from a line connecting the outer canthus of the left eye with the same mastoid process above to a line on a level with the larynx below. From side to side the mass extended from the right corner of the mouth to the left mastoid process. The left eyelid was very œdematous and the eye closed. From the wing of the nose on the right side to the middle of the body of the jaw was two and three-fourths inches. Between the same points on the left side was six and a half inches. The skin near the point of the chin was red, tense and evidently infiltrated. The growth moved with the jaw and involved it from the canine tooth on the right side to the articulation on the left. The great vessels of the neck appeared to be merely pushed backward. The floor of the mouth was extensively infiltrated, but the tongue had escaped, being pushed far back and to the right. The woman had the cancerous cachexia, complained of sleeplessness and constant pain.

Operation.—On January 12th the patient was anæsthetized, and the tumor removed by Dr. J. B. Murdoch, assisted by members of the staff and the residents. An incision was made from a point in front of the tragus, along the position of the body of the jaw, to a point one-third of the distance from the symphysis to the angle on the right side. An incision was then made to include the affected integument. A third incision was made through the median line of the lower lip. The facial artery on the right side was secured and twisted at each extremity. On the left side it was wanting, having been absorbed from pressure. A number of other vessels required torsion. The integument was then reflected upward and downward from the original incision. The body of the jaw was divided with the saw at the position of the canine tooth on the right side. Traction of the mass toward the left put the tissues at the root of the tongue on the stretch. These were divided, separating the tongue from the diseased parts. The tip of the tongue was then transfixed by a stout wire, and the organ drawn forward by it. Strong traction of the jaw toward the left was continued, the dissection carried on from within and the jaw disarticulated. All of the jaw to the left of the right canine tooth was then removed, bringing with it the diseased mass. During the operation there was comparatively little arterial hemorrhage. There was considerable venous bleeding from the large cavity left by the removal of the tumor. This was checked by the actual cautery and persulphate of iron. The cavity was filled with absorbent cotton, and the edges of the flaps united with silver wire and hare-lip pins. The incision was sealed with compound tincture of benzoin.

The weight of the growth was twenty-one ounces. Microscopical examination showed it to be a sarcoma, of the round-cell variety.

In the evening of the day of operation her pulse was very weak and beat 144 to the minute. Her tongue was so well under control as to warrant the removal of the wire. She swallowed, with considerable difficulty, a sufficient quantity of beef essence and milk, which was conveyed to

the pharynx through a soft rubber tube. The œdema had entirely disappeared from the eyelid. Morphia, in one-sixth grain doses, was given hypodermically. During the first two days the only inconvenience was from accumulation of saliva in the throat, which was frequently removed with sponge probangs. The cavity was frequently disinfected by syringing with a four-grain solution of potassium permanganate. Feeding was diligently attended to. At the end of the second day the dressings were removed. At the end of the third day the skin flaps were found united, except at one point used for drainage. The cotton was then removed from the cavity inside the mouth. There had been no hemorrhage whatever since the operation. Her pulse came down to 120 per minute. Her maximum temperature was 100.2°.

On the eighth day she had swelling of the tongue, which disappeared in thirty-six hours. On the thirteenth day she developed a sharp attack of facial erysipelas which lasted a week. At the end of the third week she was able to go about the ward, she had gained flesh, her health was much better than before the operation, and she was almost free from pain. The growth, however, was evidently returning, the hollow of the cheek having almost filled up. One month from the time of operation the tumor was growing rapidly, the integument being tense and infiltrated. She was removed from the hospital on February 13th, further operation being thought unadvisable.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, April 6th, 1882. The President, Edward L. Duer, M.D., in the Chair.

Removal of the Uterus for Fibroid Tumor; Death; Autopsy.

Dr. E. E. Montgomery reported the following case, which had been under his care at the Philadelphia Hospital.

Sarah B. (colored), age 46, widow, native of New Jersey, of temperate habits, has been an inmate of the Philadelphia Hospital for nearly three years. She entered the gynecological ward about the last of February, soliciting the removal of a large abdominal tumor.

The establishment of her menstrual function was attended by severe hemorrhages, but soon became regular. The menses ceased at one time for five years. She has not menstruated for two years. She was never pregnant.

The growth of the tumor, which began eighteen years ago, she attributed to a kick in the abdomen from her husband. The tumor soon acquired great size, filling up the abdomen and pressing against the diaphragm, causing great distress. She has been treated by means of hypodermic injections of ergotine, and later by the earth treatment. The latter was followed by a slight reduction, possibly due to the rest in bed. When she came under my care the abdomen was more prominent than if at full term of pregnancy. Owing to the woman's emaciation and the loss of muscular power in the walls of the abdomen the mass had settled down into the lower part of the cavity, encroaching but little upon the portion above the umbilicus. A fluctuating surface, evidently the bladder, covers the whole of the lower face of the mass. The tumor was regular in outline and about equal in size on either side the median line. At the upper part of the right side could be felt a smaller, loosely connected mass, between which and the tumor the percussion was resonant. The abdominal walls were freely movable over the tumor, but the latter could be raised or moved from side to side only to a limited extent. Examination per vaginam disclosed the whole uterus involved in the mass, which rested upon the pelvis. The sound could be passed five inches into the uterine canal along the posterior border of the tumor. The posterior lip was thin.

We evidently had a fibroid tumor which had originated in the anterior wall of the uterus and had drawn the bladder up with it as it grew.

In view of the large size of the mass, the anxiety of the patient for its removal, and her general condition, it was decided, after a staff consultation, to make an exploratory incision, and if the adhesions were not extensive above and posteriorly, proceed to the complete removal of the tumor and uterus.

The patient was kept quiet in bed one week, and sulphate of quinia, three grains, tincture of the chloride of iron, thirty drops, were given three times a day. The bowels were regulated by the use of compound liquorice powder. The urine, examined by one of the resident physicians, was found alkaline and contained no albumen.

Operation.—March 17th. Assisted by my colleagues, Drs. Duer, Warder, Parish, Musser and Hatfield, I proceeded to perform the operation under antiseptic precautions, using thymol spray. An incision three inches long was first made down to the tumor and the hand introduced. No adhesions were found above and but one band posteriorly. The bladder was spread out over and closely adherent to the tumor anteriorly. The opening was now extended to the symphysis below and the umbilicus above, and the tumor with some difficulty lifted through. The peritoneal covering of the tumor was burned through with Paquelin's thermo-cautery and the bladder dissected off. The capsule was then raised on either side, permitting ligatures to be passed beneath the broad ligaments. The lower portion of the cervix was then tied in two sections, both surrounded by ligatures, and the mass removed. Although the hemorrhage had not been excessive the condition of our patient now became critical. The pulse was very feeble, indeed, scarcely perceptible; respiration infrequent and sighing. It was only through the persistent care of Dr. Parish in the use of hypodermics of whisky and ammonia and hot water applications over the chest that she survived until the wound could be closed. She was placed in bed and surrounded by hot bottles, ergot and digitalis were given hypodermically, and whisky by the mouth and rectum, but without counteracting the effects of shock. She died two and a half hours after the operation.

At the autopsy a couple of ounces of bloody serum were found in Douglas' cul-de-sac. The kidneys were small, soft, flabby, and upon being opened were found dilated into sacs, the structure of them being largely destroyed. One was full of pus. The ureters were greatly dilated. They were not injured in the dissection for the removal of the mass. The heart was contracted, pale, and empty of blood. The ligatures had been applied around the cervix, one and a half inches above the os.

The tumor was a solid mass, weighing sixteen pounds; its longest diameter, laterally, quite regular in outline, presenting from the right upper surface a smaller mass with an elongated pedicle.

Aside from the necessity of placing such cases upon record to obtain correct statistics, it is of special importance as an illustration of the advantage to be derived from a careful study of the condition of the renal organs previous to the operation, and the increased gravity given by any symptoms that would cause us to suspect a renal lesion. We made no microscopical examination of the urine, so the presence of pus escaped notice, though its presence should have been suspected from the alkalinity of the urine.

Dr. B. F. Baer considered the examination of the urine a very important point, as albuminous or purulent urine is always a sign of danger.

Dr. H. Beates remarked, that in testing for albumen in urine by means of Hellen's test, he had noticed a singular fact in some instances where the urine was alkaline or but very faintly acid. If the acid was added to the urine before boiling no precipitation occurred, but by reversing the test, boiling first and adding the acid afterward, the presence of albumen was shown.

Dr. Montgomery, in closing the discussion, remarked that, although at the autopsy one kidney was found full of pus, none had ever been observed in the urine. This was, perhaps, due to occlusion of the ureter from pressure by the tumor. If pus were present in small quantity it might be considered to arise from cystitis from pressure on the bladder. But if urine is repeatedly found to be alkaline when no alkalies have been administered, it would indicate the presence of pus although none were found.

Editorial Department.

Periscope.

Occlusion of the Canal of the Os Uteri.

In the *North Carolina Medical Journal*, Dr. T. B. Wilkerson reports the following case:—

Mrs. E. L., married, aged 34, the mother of two children, of a nervous temperament, with a hereditary tubercular diathesis, consulted me in regard to a uterine deformity. She suffered from all the nervous phantasia that the female system is heir to, dating the beginning of her troubles from the birth of her last child, six years ago, at which time there was a rupture of the left side of the external os uteri. Shortly after her labor the following symptoms commenced, and from that time to the date of operation, scarcely an hour out of the twenty-four, during each day, has she been free from pain. These paroxysmal attacks were liable to take place at any moment, beginning with a premonitory darting pain in the lower portion of the pelvic region, extending to and along the middle of the sacral region. There was also a slight hacking cough, intense dyspnœa, with a troublesome smothering sensation, as if a heavy weight was resting on the thorax; excruciating pain in the præcordial region, nausea and headache. These phenomena were greatly increased at the commencement of each menstrual period, attended with severe bearing-down pains at the bottom of the abdominal cavity, closely imitating the throes of labor; and notwithstanding these strong expulsive efforts, hardly a stain of the monthly flow could be discerned.

The patient was placed in Dr. Sims' position, and with his speculum introduced, a good view of the parts was given. The cervix presented an appearance as if it had been cleanly excised, leaving no lips, and the cervical canal was thoroughly occluded. On the outer left side, about one-quarter of an inch above the marginal edge of the cervix uteri, was a very minute fistulous opening that, with care, a small sound, the size of an ordinary pocket probe, could be made to enter for one and a quarter inches; beyond this point the instrument could not be made to pass. The uterus and vagina were exceedingly sensitive. It was decided to operate. Accordingly, a duckbill speculum was introduced; a long tenaculum was engaged in the upper anterior surface of the neck; a small grooved director was then passed into the fistulous track on the left side, until its point was arrested on the opposite surface. A narrow, conical-shaped knife was then passed along the groove of the director to its terminal point. The knife and guide were then carried to the right, a little beyond the central point of the neck, the knife dividing, in its passage, the intervening tissue of the cervix, in a transverse median line. While the knife was held stationary, the director was carried onward to the fundus. This was done in order to be certain that the incision corresponded with the normal canal. The director being then slightly withdrawn, the knife and guide were passed up until the cavity of the womb was reached, slightly nicking the constricted canal. These instruments being withdrawn, and their positions reversed, the left side was treated in a similar manner. This left a straight, cone-shaped canal leading to the uterine cavity. After arresting hemorrhages, an intra-uterine stem,

two inches in length, and about the diameter of a large gum male catheter, was inserted in the canal—the stem being held in position by one of Fowler's pessaries, with a piece of black silk cemented on the under surface of the cut, these instruments being first coated with carbolized glycerine. The patient was confined to bed for ten days. The stem was allowed to remain in for six days, and a large-sized gum catheter was passed every third day afterwards, until the time of the next monthly period. Internally, immediately after the operation, she was given, thrice daily, the following pill:—

℞.	Acid. carbol.,	gtt. xij	
	Pulv. opii,	gr. vij	
	Quiniæ sulph.,	gr. xij.	M.

Ft. pil. No. xii.

The vagina was thoroughly washed out, twice a day, with carbolized lead and opium water. No inflammatory symptoms supervened, while the previous nervous phenomena disappeared. The new outlet remained patulous, without any contraction in its calibre.

In such cases, thorough quietude of the body in a recumbent position, and the fixing of the womb, by means of a properly adjusted cup-pessary, so as to prevent any to and fro movement of the intra-uterine stem against the side of the wounded canal, add much to the chances of a favorable result; for upon the proper maintenance in situ of this intra-uterine instrument depends the future hope of a patulous condition of the organ.

Transfusion.

The *Medical Press and Circular* thus discourses about transfusion:—

Transfusion is to-day by no means a rare operation, and medical men have fully recognized the legitimacy of expecting favorable results from it when practiced under favorable conditions. Those conditions consist in keeping the blood to be injected from coagulating, from cooling, and from the contact of air and the substances it contains. Of all the procedures invented to attain these ends, that of Dr. Roussel (Geneva) merits the preference, in that it has, in his hands, fulfilled all the requirements necessary to the success of the operation. Dr. Roussel, a few days ago, in Paris, performed transfusion. A woman, aged thirty-five, had already five children and two miscarriages. In December last she was six months pregnant, and suffered a great deal. The abdomen was enormous, and she distinctly felt the movements of the child. Two medical men who examined her, believing that they were in presence of an ovarian cyst, sent the woman to Dr. Peau, the celebrated ovariotomist. M. Peau recognized at once pregnancy, and as labor had prematurely set in, the woman, refusing to stay in the hospital, was transferred to the house of a midwife, who immediately broke the membranes, giving issue to nearly 20 quarts of amniotic fluid. Twins were successively and easily delivered; one of them lived a couple of hours. The loss of blood was no more than usual, and all appeared to go on well.

On the 1st of January, the eighth day after the delivery, the woman was seized with flooding, which was apparently arrested by plugging, but, as was afterwards proved, the hemorrhage still went on in the cavity of the uterus. Ten days afterward another attack of hemorrhage occurred, but more serious than the first, and was followed by syncope, convulsive movements, etc. Ergotine and cold aspersions with the horizontal posture mastered it, but the patient was blanched, cold, and affected with cough, accompanied by continued fever. The pulse was 130–140; vomiting, frequent diarrhœa, and complete loss of appetite were the other symptoms observed. The patient was attended by four medical men, including M. Peau, who believed that some uterine fibroma was the cause of the hemorrhage.

On the 31st of January, becoming worse and worse, the woman desired to be brought to her own home. Bismuth, morphine, iron, pepsine inhalations of oxygen, etc., were ordered. The patient, although no new attack of hemorrhage occurred, became weaker and weaker, the vomiting was frequent, and the diarrhœa came on every hour. The fainting was produced every time she attempted to sit up, the cough became more frequent, and the respiration was insufficient. Death was evidently at hand.

At this stage transfusion (direct) was recommended, as a last resource. Dr. Roussel was sent for, and on his arrival found the patient in the following condition: Barely conscious, cold, pale as a corpse, veins invisible, pulse 140, and thready. The heart and lungs were healthy. On the 7th of February, and at five in the evening, the patient being in the position above described, with exception of the pulse, which was now 150, the operation was performed. The sister and the husband of the woman offered their arms, but Dr. Roussel, on inspection, refused the offer, and on inquiring if there was not some large workshop in the neighborhood, hastened to one indicated, and having explained to the workmen the nature of his visit, several came forward ready to give their blood. A young man, small and robust, was chosen. Arriving at the bedside, the transfusor was washed in warm water to which a little soda was added. The thorax of the patient was uncovered, and the left arm was lying straight down by her side. After having mapped out with ink the course of the artery at the bend of the elbow of the young man, the transfusor was applied over the median vein, the same vessel was opened in the arm of the patient, and the canula of the instrument inserted as soon as all the air was expelled from the transfusor. This was affected by plunging the bell of the instrument in warm water, which, by means of the ball pump, was sucked up so as to completely fill the tube, expelling all the air. The two subjects were now united by an uninterrupted canal, through which the blood was allowed to flow gently. After four ounces were injected, the patient drew a long breath, and on being questioned said that she felt a sensation of warmth going up from the arm to the chest. As soon as six ounces were transfused the operation was arrested, as a slight convulsive movement was observed in the patient. The wound in the arm of the man was dressed and he returned to his work.

As to the patient, color was observed in her hitherto blanched cheeks, her lips were red, and her eyes brilliant. She spoke with strength and vivacity. She felt herself strong and well. Dr. Roussel having warned her that a shivering generally came on (due to the reëstablishing of the equilibrium of the vasomotor system) a short time after the operation, which would be followed by profuse sweating and refreshing sleep, hot tea and rum were held in readiness. In half an hour the shivering came on; the skin, which had been warm, became cold; the pulse, which stood at 100 after the transfusion, now went up to 140. Hot drinks were given in abundance, and after twenty-five minutes the body became more warm, and soon perspiration was abundant. As night came on the patient slept a broken sleep, yet the following morning she felt comparatively well, and during the day was able to partake of nourishment six times, and receive visits. The *bien être* continued, and on the 12th of February, or five days after the operation, the woman got up for an hour or two, and to-day, the 25th of February, the convalescence is complete.

Dr. Roussel, who has already practiced 128 transfusions, comes to the following conclusions: 1. Injection into the veins of a liquid other than blood is followed rarely with good results; 2 Transfusion of the blood of an animal of a different kind is always hurtful; 3. Transfusion of the blood of the same kind by the indirect method is very often unsuccessful; 4. Transfusion to succeed must be direct.

Division of the Neck of the Femur.

At a recent meeting of the Surgical Society of Ireland (*Medical Press and Circular*), Mr. W. Stokes presented the following case: A boy aged 14 was admitted into the hospital, March 1, 1881. He was fairly well nourished. The right thigh and leg were, however, much atrophied, and this process involved largely not only the soft structure of the limb, but also the bones, arrest of development of the tibia on the affected side, as well as the femur, being well marked. The thigh was strongly flexed, and rigidly fixed in that position, which rendered the limb perfectly useless. The affected limb was three and one-eighth inches shorter than its fellow. On the lateral and posterior portions of the upper part of the thigh were numerous cicatrices of old sinuses that had discharged very offensive pus for several years. The disease commenced nine years before, as the result of an injury. During this time he had been treated with blisters and extension, and on one occasion excision of the head of the bone was proposed, but his mother would not consent to it. It was decided to divide the neck of the femur, and the operation was performed as follows: The patient being etherized, a straight incision was made behind the great trochanter, commencing three-quarters of an inch above it, and carried downward for a distance of three inches and a half. From the upper portion of the incision it was carried in a curved direction, upward, forward, and then slightly downward, the whole incision being thus somewhat crozier-shaped. This line of incision was adopted partly to give plenty of space to determine the actual condition of the parts, and partly because it is a convenient one to adopt, in case it is deemed desirable to excise the head of the bone. The soft structures being then dissected off the trochanter and portion of the bone immediately below it, by scalpel and periosteal raspatory, the finger was passed into the wound, to ascertain the condition of the head and neck of the bone. The former was found to be rigidly fixed to the acetabulum, the latter shortened and atrophied. There was no evidence whatever of any softening of any part of the bone. A medium-sized osteotome was then passed in, and by a few sharp taps of a mallet the neck of the femur was divided. Notwithstanding this, it was impossible to satisfactorily straighten the limb, owing to muscular contraction, chiefly of the adductors. A subcutaneous tenotomy at once overcame this obstruction and the limb could then be extended. The wound was carefully washed out with a 1–40 solution of carbolic acid, a drainage tube inserted, and the edges brought into close apposition with numerous points of interrupted catgut suture. The usual Lister dressings were then applied. The wound healed without pus production. During convalescence a moderate extension of the limb was kept up, mainly by the double-threaded screw extension splint. After six weeks the patient was able to get about the ward without crutches, by the aid of a stick. This latter was subsequently discarded and the patient soon after returned home. Three months after the patient was healthy and strong, and able to walk with facility, without stick or crutch. He suffered no pain, and there was distinct evidence of the formation of a false joint at the site of the operation. The muscular development of the affected limb was greatly improved, the limb straight, and the patient stated that he was able to walk, without inconvenience, a distance of over three miles. The credit of having first suggested and practiced this operation for the cure of this deformity, formerly considered a condition that necessitated amputation, is due to Dr. J. Rhea Barton, who performed the operation in 1826, in the case of a sailor, by exposing the trochanter by means of a crucial incision and dividing it with a saw. In the opinion of the operator, a false joint is much more likely to follow division with a chisel, than a saw, because, when the latter is used fragments of bone may be left in the wound, which, acting as centres of ossification, may possibly be antagonistic to the formation of a pseudo-arthrosis.

Paralysis of the Uterus.

In the Peoria *Medical Monthly*, Dr. Romaine J. Curtis relates the following cases:—

Case 1.—Mrs. ——, a multipara, aged 37, was taken in labor, and two hours after sent for me. When I arrived something had suspended the rhythm of parturition, which I could not discover. The os was partially dilated and dilatable. Child alive, with vertex presentation. Patient stated she was always delivered by forceps, because of cessation of labor pains, and I was requested to deliver in this manner. I advised her to wait

The next day I found the pains strong, but to my surprise they soon stopped abruptly, the os being fully dilated and the bag of waters protruding. I again left her, and she passed a comfortable twenty four hours, when labor was again established. I visited her, taking an electro-magnetic machine. As I expected, pains again ceased when the head was in the pelvis. The patient clamored for ether and forceps, the propriety of which I could not deny, and in great anger the friends sent for another physician. I had forceps with me, but I wanted the patient to go through her labor. I applied the electricity, one pole on each side of the uterus, and half way between the pubes and umbilicus. The uterus responded instantly, and I could bring on contraction at will, and continue it as long as I kept the poles applied. To test the case further I gave ether and continued to conduct the labor, which was soon completed. My friend Dr.——, arrived too late to witness the birth.

Case 2.—I was sent for at night to attend Mrs. ——, multipara, aged 38 years. Labor progressed normally and rapidly for two hours. The os was well dilated, bag of waters protruding, when pains abruptly stopped, without discoverable cause. After using friction to uterus through abdominal walls, and giving ergot, I ruptured the membranes, and waited two hours without a sign of labor being resumed. Counsel was now called, who used friction to uterus, body and cervix, for some time; gave gr. x quinine, more ergot, some whisky, and then, as labor was not resumed, advised waiting, and went home. Thinking the case over I sent for the machine and applied as before. The current was rather strong, as all hands were in ill temper. The patient screamed with pain, a contraction of the uterus followed, and labor was completed with one pain.

Case 3.—Mrs. ——, aged about 26 years, a multipara, was delivered after six hours' labor. I removed the placenta by Crede's method, applied a "binder" after contracting the uterus, and left her. In two hours was sent for in great haste, and found the patient with concealed hemorrhage. I removed clots and secured contraction of uterus, but found that I was obliged to maintain pressure to maintain contraction, and that the bleeding was continuing. Two hours were spent giving ergot, carbonate of ammonia, and compressing the uterus, before I thought of electricity, and another hour before the machine could be obtained and made to "work," and all this time the patient was losing blood. The use of the induced current set matters right.

Osseous Degeneration of the Eye.

Dr. Martin F. Coomes reports the following case in the *Medical Herald:* Miss M. L. O., age 32 years, consulted me in the latter part of July, 1881. She complained of constant and severe pain in the left eye, and along the course of the supra-orbital branch of the fifth nerve. The pain was constant, but worse during the day than at night, and nothing but opiates, internally, seemed to possess the power of alleviating it. Vision, in the diseased eye, was completely destroyed by an inflammation, during her early childhood. She said the eye had been painful, at times, for three years preceding this last attack, which occurred in the spring of 1881. The right eye was weak and irritable; vision equaled $\frac{20}{40}$. In the left eye T n + 3, while in the right T n + was observed. There was complete occlusion of the pupil of the left eye, with a pink zone encircling the cornea, such as is met with in cases of irido-cyclitis.

Not being able to make an ophthalmoscopic examination, and taking into consideration the great tension and persistent pain, and knowing that the majority of such cases of irido-cyclitis, and, in fact, most all of the chronic inflammations of the uveal tract, are relieved by iridectomy, that operation was performed July 20, 1881. The iris was extremely rotten, and it was with great difficulty that I succeeded in removing a portion of it. The operation relieved the unpleasant symptoms for three or four weeks, but the pains and tension gradually returned with as much severity as before.

On the eleventh of November, 1881, the patient was chloroformed and the eye enucleated. During the operation it was ascertained that the posterior portion of the globe presented to the finger a sensation of the hardness of stone, while the anterior portion was elastic, and presented nothing unusual. The patient made a good recovery, and is now free from pain, and the irritation in the fellow eye has entirely subsided.

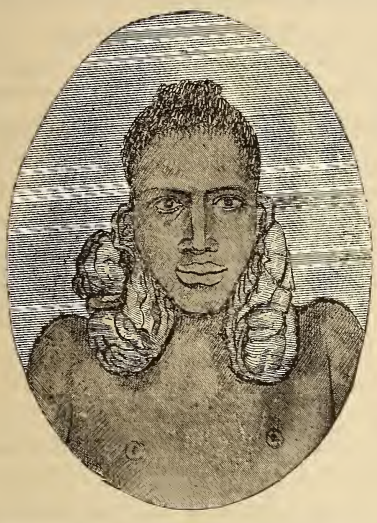
Upon investigation, the sclera of the enucleated eye was apparently normal in structure, with adhesions to the conjunctiva. The cornea was perfectly healthy in appearance; the choroid was entirely absent. From the equator forward to the ciliary body, at some points, the connective-tissue remains of the choroid was in a tolerable state of preservation. The ciliary processes were, apparently, all present, but firmly adherent to the mass which represented the hyaloid and vitreous body. The lens was shrunken, and its periphery encircled by a thin sheet of osseous tissue, corresponding to the capsular ligament.

The hyaloid membrane and choroid seemed transformed into a bony shell, having a round posterior opening about the twentieth of an inch in diameter, corresponding to the porus opticus, as was easily determined by the presence of the central vessels of the retina, surrounded by a few nerve fibres. This opening was surrounded by apparently healthy, compact bone, extending forward nearly to the equator of the globe. The remainder of it, from this point forward, in some portions, was interspersed with chalky deposit, and in many places the osseous structure was entirely absent. Near the equatorial line it became very thin. The interior of the shell was funnel-shaped. Some portions of the inner surface were very hard, others were of the nature of thin cartilage, and others were apparently composed of threads of osseous tissue, presenting the appearance of the pith of certain medullated plants.

Puncture of the Ears

Wm. Allan thus writes to the Dublin *Journal of Medical Science.* The following interesting case came under my care in January, 1882: B.

Bahoo, aged sixteen years, presented himself for admission into the Victoria Hospital, in order that he might receive surgical treatment for two large auricular growths. Through an interpreter the following history was obtained. He had his ears pierced for earrings when eight years of age. Shortly after the operation the tumors appeared, and when examined had attained the following proportions. The right tumor, attached to the lobules of the ear, and having cutaneous attachments to the parotid and mastoid regions, meas-



ured from above downward nine inches, and in circumference fourteen inches; lobulated, hard and firm to the feel. The left tumor, smaller than the right, and having a somewhat similar attachment, measured from above downward 9 inches, and ten inches in circumference. A small portion of the posterior inferior part of this tumor exhibited leucoderma, while the anterior inferior end of the right tumor showed signs of commencing degeneration. After placing him for a few days on preparatory treatment, I ligatured the base of the right tumor with some little difficulty ; the first ligature, though strong, giving way. The nutritive supply of the tumor having been interfered with, I dissected it off from its attachments, removing a portion of the ear and surrounding tissue, to prevent, if possible, a recurrence of the growth ; weight on removal, two pounds twelve ounces. I repeated the same operation with the left tumor, but passed a double ligature through the centre of the pedicle, on account of its size, tying it anteriorly and posteriorly ; weight on removal, one pound twelve ounces. There was a fair amount of arterial hemorrhage, on account of the arteries supplying the tumors being unable to contract ; pressure on the common carotid and torsion were of service. The after treatment consisted of rest and a pill containing opium and quinine. The parts were washed daily with carbolic acid lotion and afterwards dressed with zinc ointment. No glandular enlargement existed at any time. The growths are probably of a fibro-plastic nature.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the Thirty-ninth Annual Report of the Mount Hope Retreat, for the year 1881. The institution, we are glad to see, is satisfactorily conducted.

——Is the Ovarian Cell Pathognomonic? By William A. Edwards, M.D. A very valuable reprint from the *American Journal of Medical Sciences* for April, 1882.

——The Century and the School. A lecture read before the National Educational Association, at Atlanta, Ga. By F. Louis Soldan, Principal of Normal School, St. Louis, Mo.

——Abdominal Section in the Treatment of Ulceration and Perforation of the Cæcum and the Appendix Vermiformis. By William A. Byrd, M.D., Illinois. Reprinted from the Transactions of the American Medical Association.

——Anæsthesia and Non-anæsthesia in the Extraction of Cataract; with some practical suggestions regarding the performance of this operation, and comparative statistics of two hundred cases. By Hasket Derby, M.D. A very interesting little pamphlet.

——The Case of Guiteau ; a psychological study, by George M. Beard, M.D., of New York, comes to us as a reprint from the *Journal of Nervous and Mental Diseases*, January, 1882. In this essay he maintains that "Guiteau was taken insane at the age of eighteen years, while attending school at Ann Arbor, and has been insane ever since." "The special type of his insanity is what is commonly and correctly called religious monomania."

——Lumbo-Colotomy in the New-born, for Relief of Imperforate Rectum. By William A. Byrd, M.D., of Quincy, Ill. This comes to us in the form of a reprint from the *St. Louis Courier of Medicine*, December, 1881. The author, quoting from Van Buren, says: "Perhaps the best answer to those who object to an inguinal anus, on sentimental grounds, and the best proof of its practical efficacy, is to be found in the case of the lady, related by Mr. Curling, who had been subjected to the operation in 1816, and who, at the age of forty-three, enjoys the best health, goes into society and attends balls, and no one would suspect her to be the subject of any infirmity. She is married, has borne four children, and her pregnancies and labors have been quite normal. She never experiences any pain in the part."

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8 25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

RAILROAD SURGEONS.

We have had something to say about Steamship Surgeons; now a few words about Railroad Surgeons. There was recently held at Decatur, Illinois, a meeting of the Surgeons of the Eastern Division, W. St. L. and P. R'y.

Two papers were read by J. T. WOODS, M.D., Chief Surgeon. In the first, he sketched the origin and history of the organization. It seems that when, in April, 1875, he suggested the question of surgical service on the Wabash, to its President, the outlook was very gloomy. It was deemed impracticable, because it was believed that it would lead to abuses. It would cause the employés to expect too much from their employers. Finally, Dr. WOODS received consent to try the experiment. The first point was to find a good and reliable surgeon, in each of certain selected localities, who would serve the Company on such conditions that, as a whole, advantage would accrue to the employers, the employé and the medical man himself. At first, much difficulty was experienced. Opposition was experienced from the employés themselves, who often preferred to choose their own surgeon, in lieu of the one selected. This natural and pardonable timidity of employés has gradually melted away, as they have not been slow to note that men who are expecting and hold themselves prepared for this special duty are none the less careful, and are, because of their assumed responsibility, more ready with appliances, in greater perfection, than those who are otherwise wholly engaged. They have also learned that each, in his locality, stands among the very first in his calling. In the same direction, and of vital importance alike to the employer, the patient and surgeon, lies the fact that familiarity with this species of work leads to fewer unsatisfactory results than would be otherwise expected. Those who have had much experience in railway surgery are aware that these cases, as a class, are peculiar, and, to attain the best results, especial attention, coupled with practice among them, is of inestimable value. These, among many others, are the advantages brought to the service of injured employés, as well as to the company, by their medical officers. We know not whether the great Pennsylvania system has any regularly organized medical department or not, for Dr. WOODS says, "On numerous lines, more or less system has been attempted, but the work was so desultory and unsatisfactory, and, finally, so expensive, that it usually has either gradually dropped to pieces or been suddenly abandoned, as is the case on the whole system controlled by Mr. VANDERBILT, in which the company now take no care of any one, and the medical man who serves the injured must look to the patient for pay—the maimed men, who have not the means, however well disposed."

It is a well established fact that employés are always more attached and more faithful to an employer whom they feel has their interests at heart and will take care of them. Instinct will teach them enough for this. Again, there is always a large army of thoroughly capable young physicians who, because merely of their youth, are unable to secure any private practice. They are just as competent to cure disease and relieve

the maimed as are many of their older confrères, but men and women are unwilling to trust their lives and health in the hands of *young men.* These physicians would be very glad to accept positions in the service of railroad companies for a very moderate compensation. Thus also would the corporation secure efficient medical service at a comparatively small expense. The question really, as Dr. Woods says, is one of business. If by providing free medical attendance for their injured and sick employés, the company can feel sure that by thus caring for their interests they will derive more benefit from their labors, then can it be confidently trusted that such organizations will become general; if not, then they will be unknown, since it would be altogether too Utopian to expect corporations to be so eminently philanthropic.

CHARITY ORGANIZATIONS.

For years the streets of our large cities have been encumbered by beggars of all kinds. From the aged and decrepid blind man, with his pitiful story of a wife and six young children at home, down to the ragged urchin sent out to beg (and to become thereby inured to a life of shiftless laziness) by his worthless and generally drunken parents, all ages and sexes are to be found represented in this vast army of worthless human nature. We have now cause to rejoice that the real nuisance has been recognized at last, and that energetic measures have been inaugurated which will result in making this objectionable feature of city life a thing of the past. The physician has much interest in this evil and its proposed remedy; for one prominent reason, let us remind him of the influence for evil that may lie in the impression upon a pregnant woman of some of the truly horrible and repulsive spectacles presented by these professional beggars. The stock in trade, the capital, of these poor deformed specimens of humanity lies in their very deformities, which they make as prominent and conspicuous as possible, asking all the while for alms, and using their misfortunes to enforce their appeals. Who can say that the large majority of monstrosities are not the direct results of impressions received from these deformed beggars?

A committee of the Society for Organizing Charity, composed of our most prominent citizens, recently called upon the Mayor of Philadelphia, to solicit his assistance in the furtherance of their work.

It was then stated that the Society had extended its organization over the whole city. Every district has a superintendent, who keeps an office open at fixed hours, and who is charged with the duty of investigating the case of every applicant, and giving relief in pressing emergencies, or referring the case to the proper institution or family. They will furnish to the police department, for the use of each officer, a card with a list of the district offices of the charity organization, their location and superintendents; also a supply of tickets to be used in directing beggars to the office of the proper district. Without using harshness, the society requests the Mayor to instruct the police to give to every person found begging on the streets, in the first place a ticket of investigation to one of the district charity offices, and if such beggar shall refuse to go, or shall be found begging again, then the case shall be treated as an offence against the law, and the beggar shall be arrested and committed to the House of Correction or other public institution. They have also perfected arrangements by which all able-bodied applicants are sent for employment to the Pennsylvania Railroad Company. If a man is in such straits that he cannot wait for pay day, the society makes him a small advance as soon as he has earned it, and protects itself by a lien on his wages. The Mayor replied that he would instruct his officers to arrest all street beggars indiscriminately, and would do all in his power to aid the Society in carrying on their good work.

A similar society is being now organized in New York city, and we sincerely trust that ere long all the large cities of the country will follow this example.

We all know that there are a very large number of men and women who are naturally lazy, and who, having no self respect, do not hesitate

to beg. To such it is much pleasanter to pass the bad days of winter in some Almshouse, and when Spring time comes to stand or sit in the bright sun and receive the numerous pennies of the passers-by. This is the routine of these professional beggars. They are no benefit to society, they play no part in the general progress of human nature, they really constitute foul ulcers on the body politic, and it is high time that they should be reformed. Those that are able must be made to work; those who are physically incapacitated should be isolated and not permitted to remain objects of horror and disgust on our public highways.

BOGUS DIPLOMAS.

Personalities are usually objectionable, and are generally avoided by this journal. Occasionally, however, they become necessary, as in the present instance, to warn the public of pitfalls that may be awaiting them. The *New York Times*, of a recent date, has the following, which should be given all possible publicity by those who know and are familiar with the past history and nefarious practices of the party concerned:—

"Dr. Buchanan's most recent exploits and escapades have borne fruit quite worthy of themselves, and perhaps quite comforting to the Doctor. Some of his friends at Detroit, aided by a truly formidable, and as truly obscure, host of M.Ds., L.Ds., Sc.Ds., and what not else in the degree category, have organized a college called the Medical Department of the Detroit University, and sent out their 'annual announcement;' whether the first or the twentieth such does not appear, but evidently the first, and probably the last. It is not published at Detroit, but at Jackson, seventy miles away, and sets forth, in language which, if grammars were unknown, might be called English, that the college's aim is to remedy a growing evil; which growing evil appears to be the admission to existing medical schools of persons unprepared to receive an education, owing to the 'want of a suitable preparatory prerequisite to a proper understanding of the branches taught.'' The University has been founded in Detroit for the reason, among others, that Detroit has large manufactories and many hospitals, which furnish a great amount of 'clinical material.' Moreover, the city has a public library of over 40,000 volumes, which are free to all, and a population of 140,000 souls. Truly useful these attractions will prove for the coming students of the Detroit Medical School; for, so far as can be learned, they are the only ones that the school can offer them. We are gravely told that the college building is 'a large and commodious structure in the most desirable locality,' which locality appears to be the immediate neighborhood of a grist mill, and this 'commodious structure' a loft of the said mill. For the Registrar's office intending students are directed to a house 'just four squares west of the City Hall.' On going to the place the names of four physicians are found outside, on tin signs, beneath the words 'Institute of Rational Medicine,' while a dirty card has, in pencil, the words 'rooms to rent,' and another tin sign announces the abiding place of a 'Marriage Assurance Association.' One H. S. Thomas is the college president. He was graduated by the eminent Dr. Buchanan himself, and is now an able 'cancer doctor.' Of his faculty and trustee associates the names of only three can be found, in all Detroit, and one of them, his address being obtained, appeared to live over a manufactory of wagon grease. but nobody there knew he was a doctor. President Thomas did Buchanan a good turn when good turns were welcome to him. Buchanan found a refuge in Thomas' house, the Detroit people say, while the officers were hunting him out, just before that fortunate escape of his to the Queen's dominions."

HIGHER MEDICAL EDUCATION.

It is plainly evident that the medical profession of the United States is commencing to realize the necessity for elevating the standard of medical education. The praiseworthy action of the University of Pennsylvania has been followed by measures in New York looking toward the same end.

The New York State Medical Society has proposed two bills to the attention of the legislature, which, in substance, are as follows: When a candidate for practice has completed his preparation, and obtained his diploma from a college, before he can actually enter upon medical practice his qualifications must be verified by a higher board, not composed of those to whom he has just paid two or three years' fees, but of men who have no interest in passing him. From this body he receives a second diploma, registry of which entitles him to practice medicine in the same manner as that of his college under the present law. The proposed law applies to all medical sects, and the candidate is to be examined, not necessarily in the principles taught in the regular school only, but in those of the school under which he may elect to practice. In commenting on these bills, the New York *Times* very sensibly says:—

"Possibly no better way could be devised by the Committee on Legislation than to avail themselves of the existence of that indefinable body, with vast advisory and no real powers, the University of the State of New York. The Regents have certainly the power to confer diplomas, and it might have been objectionable to establish a sort of medical university for the purposes of the statute. One fails to understand, however, why a second diploma should be necessary, since the candidate is already well armed in that respect. It would seem, indeed, with all due deference to the doctors, that a law authorizing and directing a Governor to appoint boards of medical examiners, defining their composition and duties, and making the registry of a license or certificate from such a board a condition precedent to practice, would answer all the requisites of popular protection and meet all the requirements that are met by the bills as printed. Such a mode of dealing with the subject would not add materially to official procedure, while securing all the ends for which Prof. Jacobi and his coadjutors are laboring; ends in the highest degree desirable."

Notes and Comments.

Section of the Spinal Accessory Nerve.

At a recent meeting of the Acad. de Médecine, M. Tillaux presented the interesting clinical history of a patient in his service. She first entered the service of M. Desnos, suffering from a species of spasmodic torticollis, the head being twisted toward the right shoulder; this phenomenon was accompanied by considerable pain about the occipito-vertebral articulation.

The general opinion was that there existed functional spasms of the sterno-mastoid muscle.

M. Vulpian advised electricity, and this, with metallo-therapy, the bromide and iodide of potassium and other remedies, were employed without any amelioration in the condition of the patient, who desired an operation to put an end to her sufferings.

It was at this period that she entered M. Tillaux's service at the Beaujon Hospital; after mature consideration of the case he divided the inner portion of the sterno-mastoid muscle, very near its insertion to the sternum. This operation procured no relief; the spasms were as intense as before for eighteen months afterwards.

In the opinion of M. Vulpian, who first examined the case, the cause of these spasms lay in the spinal accessory nerve, and as M. Tillaux was of this opinion also, he decided on excising or dividing the nerve. An incision was made, parallel with the posterior border of the sterno-mastoid muscle and between two lines drawn horizontally, the upper from the angle of the jaw, and the lower from the superior border of the thyroid cartilage. The nerve was divided and the wound rapidly cicatrized under antiseptic treatment.

Considerable benefit was obtained from the operation, the face was still drawn toward the right shoulder, but the movement was not so spasmodic; the patient could control and even resist it.

The spinal accessory nerve has been studied from a physiological point of view by Claude Bernard, who considered it as essentially the nerve of phonation. In the present case M. Tillaux's patient has not manifested any change in the voice, or any defect in articulation.

Compound Dislocation of the Ankle.

A a recent meeting of the Surgical Society of Ireland (*Medical Press and Circular*), Mr. Thornley Stoker exhibited a specimen of compound dislocation of the ankle, which was so severe as to require amputation. The dislocation was of the most usual form, that of the foot inward and of the two bones of the leg outward. In addition to the dislocation and the laceration of the soft parts, the malleolus of the fibula had been fractured transversely on a level with the transverse surface of the tibia, while the malleolus of the tibia was similarly broken off from its attachment, and remained connected in its usual position, on the inside of the foot. While the fracture of the fibula was quite transverse, that of the tibia extended upward and inward. The injury was caused by a kink of chain catching round the man's leg, while the anchor was being weighed.

Supposed Ovarian Neuralgia.

Dr. J. W. McAfee reports the following case in the *Pacific Medical and Surgical Journal*, which he considers an inexcusable mistake in diagnosis, and showing the fallacy of treating symptoms. A young lady, aged 22, had suffered for six years from neuralgia of the right ovary. For the first three years the attacks were slight and irregular, gradually increasing both in duration and severity. She had received all kinds of treatment for three years without avail. She finally became quite melancholy. General health and menstruation regular. External examination revealed neither tenderness nor enlargement in the ovarian region. Examination per vaginam showed uterus enlarged, but not painful on probing. Anterior lip of cervix large, dark and congested; posterior completely denuded of its epithelial coat, and covered with

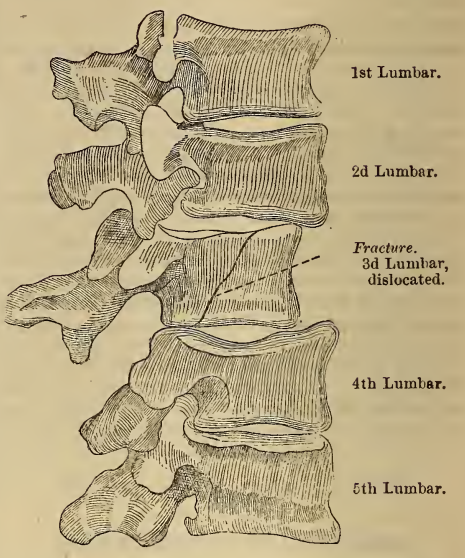
large fungoid granulations, which had a tendency to bleed on the slightest provocation. From this granular surface was poured out a thick, tenacious discharge, streaked with blood and pus. After thorough cleansing, iodine was applied, and the parts dressed with absorbent cotton and bismuth cream. Ordered a douche of one gallon of hot water to be used night and morning and discontinued all drugs. The next day the anterior lip of the os was much swollen, dark and tense; with a sharp bistoury he made several punctures, which bled freely and gave much relief. This treatment was continued for ten days without much change. It was now determined to use nitrate of silver. The stick was applied freely to the denuded surface, as well as the cervical canal. It acted like a charm; the improvement was rapid and steady. After a few days the ovarian pain had almost entirely disappeared. After eight weeks of treatment the uterus was reduced to its normal size, discharge disappeared, and the cervix was reduced to a healthy condition. The ovarian neuralgia was completely cured.

Epithelioma of the Œsophagus.

At a recent meeting of the Surgical Society of Ireland (*Medical Press and Circular*), Mr. H. G. Croly showed a specimen of epithelioma of the œsophagus. The patient, aged 60, was admitted into the hospital on the 22d of last December. It was remarkable how little pain he suffered. There was syphilis in the history of the case. On trying to swallow, spasmodic efforts were made to get food down; but it was immediately rejected. He was able to swallow a little soda-water and milk. Finally he became utterly unable to swallow anything. Gastrotomy was performed and the man died the next day. In the specimen was observed very perfect adhesions between the peritoneal surface of the stomach and the abdominal walls. The situation of the annular stricture was a little below the crossing of the left bronchus. There was no disease of any surrounding parts.

Fracture and Dislocation of Vertebra.

Dr. Isaac W. Chisholm writes to the Cincinnati *Lancet and Clinic*, that the case of fracture and dislocation of the third lumbar vertebra, which he reported in full in the *Lancet and Clinic* of September 27th, 1879, has so far recovered, a little over three years after receiving the injury, as to be able to act as salesman in a store without any artificial support whatever, and never uses a cane or crutches unless he walks a long distance. The following cut represents the seat and extent of injury:—



Sign of Pregnancy.

Dr. Delattre mentions, in the *Gaz. des Hôpitaux*, what he considers a constant sign of the beginning of pregnancy, namely, the almost complete disappearance of the phosphates from the urine. The author believes that they are condensed into the bones of the mother, forming osteophites, during the first months of intra-uterine life. During the last months, the fœtus developing rapidly, this reserve of phosphates is drawn upon, the bones of the child increase in weight, and the osteophites gradually diminish, until they finally disappear, usually after the first month of nursing. Where the mother is weakly, instead of having these reserves, she is compelled to borrow from her proper substance the necessary elements for the nutrition of the fœtus, and her strength becomes exhausted. In such cases the author recommends the use of phosphate of lime during the whole course of the pregnancy.

Cardiac Dyspnœa.

M. Sée recommends, for the relief of the constant dyspnœa present in certain affections of the heart, the following potion:—

℞.	Potass. iodid.,	gr. xv to	ʒ ss
	Chloral. hydrat.,	ʒ ss to	ʒ j
	Syr. acaciæ,	ʒ iv.	M.

To be taken in tablespoonful doses every two hours.

The choral may be replaced by 1 to 2 grains of extract of opium. When dyspnœa is not constant, iodide of potash is useful against the attacks, and inhalations of the iodide of ethyl, which succeed in asthma, may be tried.

Hypopyon.

The *Medical Press and Circular* says that Dr. Just recommends *massage* of the globe of the eye, which consists in pressing and rubbing gently the organ with the lower lid intervening. In this way he has succeeded in causing to be absorbed a purulent collection in the anterior chamber of the eye. Another oculist has been able to provoke rapid absorption when the hypopyon was mobile, by making the patient lie alternately upon the right and left side, and causing him to change position every hour.

Correspondence.

Ovariotomy—Death Third Day After Operation.

Ed. Med. and Surg. Reporter:—

Mrs. C., 48 years old, mother of eight children (one deceased). I have treated her professionally frequently, for several years (I was called in consultation eleven years ago, and diagnosed at that time metritis), for menorrhagia, pruritus vulva preceding and accompanying menstruation, profuse leucorrhœa and prolapsus uteri; also for indigestion, which last has been almost persistent since last Spring; nausea and vomiting frequent, and pain located in the epigastric region. I detected, upon examination, September 9th, 1881, a small tumor, size of hen's egg, in left iliac region, and upon my next visit she informed me that the enlargement had subsided; that she had been subject to pain and enlargement occasionally, in the same region, for over twenty years. The symptoms of indigestion continued, but she did not complain to me of pain in the iliac region again until November. I made second examination November 21st, and ascertained the tumor had enlarged rapidly and was indurated and nodulated, and ascended to a point midway between the os pubis and umbilicus. I diagnosed ovarian tumor, solid in consistency and malignant in character. Dr. Clark met me in consultation, and concurred in the diagnosis and prognosis. Prof. Peck saw the case February 5th, and stated that an operation was the only remedy, and performed the operation on February 12th, 1882, in presence of Drs. Hunter, Adair, Beck, Hill, Dixon, Dilly and myself. The operation lasted one hour and twenty-five minutes. Tumor weighed six-and-a-half pounds, fibroid in character, and attached to fundus uteri, broad ligament and left ovary. Death ensued third day after operation.

Remarks.—I presume the case would have terminated fatally if the operation had been performed sooner, judging from character and rapidity of growth and irritability of stomach. Mrs. C. was opposed to any surgical measures until after Dr. Peck saw her. C. E. Quire, M.D.

Lynnville, Iowa.

A Peculiar Case.

Ed. Med. and Surg. Reporter:—

I would like to inquire of the readers of the Reporter if the following case was not a little peculiar:—

Was called, April 25th, 1879, to attend Mrs. Addie E. G., it being her fourth pregnancy. I arrived at 8 A.M.; girl baby born at 11 A.M., A 1, weight 7 lbs. I was attending to the child, when the mother called me to her, saying she was having severe pains. I barely reached her when an odd looking tumor-like object rolled out on the bed, and my first thought was that it was some kind of a tumor, but there appearing to be something moving in it, I cut or broke open the sac or membrane, and found a second living child, with the placenta; this was a boy, and weighed 4½ lbs.; he looked like a little, queer old man; but he never seemed to thrive, and died about three weeks later. The mother was a large, fleshy woman, and weighed about 280 pounds. The peculiarity of this case is that the second child was enclosed in a sac or membrane, the sac being entire, smooth and unbroken.

I have practiced medicine only thirteen years, and have not more than between 50 and 60 cases of midwifery a year, on an average, so that perhaps there have been such births; but it appeared queer to me, and I have often thought of it, and at last concluded to send you an account of it, just as it happened, copied from my note-book.

Lincoln, Me. C. Fuller, M.D.

News and Miscellany.

Kentucky State Medical Society.

The twenty-seventh annual meeting of the Kentucky State Medical Association was called to order by the President, Dr. J. W. Holland, at 2.30 P.M., Wednesday, April 5th, 1882, in the rooms of the Polytechnic Society of Kentucky, in the city of Louisville, a large number of the representative men of the profession from all parts of the State being in attendance.

The minutes of the previous meeting having been published in pamphlet form by the Permanent Secretary, Dr. Lewis S. McMurtrie, and distributed to the members within a few days after the preceding meeting, their reading was dispensed with and the report of the Committee of Arrangements called for.

Dr. Dudley S. Reynolds, chairman of the committee, reported, in a few brief sentences, that the adoption of a new Constitution at the previous meeting, by which many of the long-established usages had been changed, rendered it somewhat difficult for the Committee of Arrangements to provide adequately for the present meeting. The committee, however, after much deliberation, had concluded that the design of the State Association is to assemble for interchange of professional opinions upon live questions, and to advance the material and scientific interests of the profession in Kentucky.

The reports of the officers and standing committees were all received, after which the President, Dr. J. W. Holland, delivered an introductory address.

Dr. Holland congratulated the Society upon the auspicious surroundings attending this opening of the meeting, and regarded it as a matter for congratulation that the nomadic habits of the Association had begun to be abandoned. He referred to the disadvantages attendant upon the previous migratory customs of the Society, at the same time not neglecting to discern the fact that regret must follow the departure from long established customs and the varied scenes and associations that attend a change of situation for the brief period allotted to the meetings of the Society.

State medicine claimed a worthy notice, in the discussion of which the President took occasion to emphasize the necessity for more complete vital statistics and better regulated returns of marriages, births and deaths, in order to facilitate the harmonious action of united efforts in sanitary regulations.

The well-worn and perplexing theme of the regulation of practice was not forgotten, and the previous inefficient acts of the legislature were referred to. He concludes that thirty years' experience has taught us not to put much faith in acts of the legislature as great moral levers. As an evidence of the necessity for some sort of regulation, the Secretary of the State Board of Health for 1879 reported, as among the unclassifiable causes of death, "falling of the brain," "ulcer of the brain," "nervous irritability," "bold hives," "diseases of females." Within the year the mortuary reports of Louisville have several times quoted (may the good Lord deliver us) "delicacy" as the cause of death.

Concerning the recent action taken by the New York State Medical Asscciation, Dr. Holland said, "In effect it approves of any of the members of that Society and others in affiliation therewith, when they meet in professional comity persons of the class considered heretofore as outlaws."

In concluding, the President said, "The forty gentlemen who organized this Society had in view the promotion of the honor of the profession, and crediting them with unusual zeal in taking that first step, let us be guided by the precepts they then endorsed, and fired by the examples they have since furnished us. Within the month, the death of one of them prompted in me the thought that the title to the regard of posterity which Dr. Foree held in common with all healers and teachers is strengthened by the additional claim that he was one of the first in our State to urge medical association for the high aims we posessss. His individual life among us has come to an end, but in the corporate life of the humane organization which he helped to establish and maintain he shall find an earthly immortality. Other names then enrolled, of men no less deserving of praise, have been marked with the sign that denotes an eternal absence from its councils. In the texture we weave, their many colored threads, brought once and again into the pattern by the shuttle of time, shall give neither hue nor form again. In our annals they may have left little record to boast of, and even in their own journals little is written of their worthiest deeds. Turn the pages of their visiting lists and a monotonous row of crossing lines is the only trace you will find of many acts of benevolence, of the light and joy they brought to many thresholds. Nothing but lines to tell the story of anxious watching by the couch of pain and the sweet repose secured by the healer's art. Nothing but lines to mark the hard fought field which restored some regal mind to its lawful throne. Nothing but lines to stand for the dearly prized lives turned back to us as they were about to pass the gateway that lets men out from the golden circuits of the sun."

The society then adjourned till Thursday morning.

THURSDAY'S SESSION.

The morning hour devoted to the transaction of miscellaneous business having been consumed by the reports of the various committees, the regular proceedings of the day were opened by a report on the Progress of Surgery, by Dr. W. O. Roberts, of Louisville.

The question of antiseptics, Dr. Roberts said, occupied no more settled ground in the professional mind than it did immediately after its introduction. In abdominal surgery their use has been abandoned entirely by Dr. Keith, of Edinburg, though he still places implicit confidence in their efficacy in other operations. The general drift of professional opinion, however, seems to favor the reliance rather upon the drainage tube than upon any use of antiseptics. In abdominal or Fallopian pregnancy the year just passed has witnessed a revolution in reference to the disposition to be made of the placenta after operation. Instead of its removal as before, it is now insisted upon, by many leading authorities, that it shall be allowed to remain within the cavity, to await the process nature substitutes to detach it on the one hand or remove it by absorption on the other, or render it innocuous by encapsulation. Previous to the advent of the doctrine of antisepsis the operations of nephrotomy and nephrectomy had not been frequently performed, and they had been attended by a large mortality. Since its promulgation, probably because of greater care and cleanliness, these operations have been more frequently performed, and altogether very much more frequently successful. Abdominal transfusion has been established as a legitimate procedure by actual experiment, the hæmoglobine having risen in twenty-four hours from 38.8 parts to 57.9. In the treatment of gunshot wounds of the abdomen the importance of operative interference to cleanse the cavity is now emphasized, and Dr. Marion Sims has declared that those who practice the old expectant plan of management should be held accountable for non-interference, since such cases so uniformly result disastrously.

Dr. Roberts referred to several other points in detail, but unfortunately, the paper, though interesting, was not discussed.

Dr. Wm. H. Wathen next came forward with a paper on "Abdominal Section for the Removal of the Fœtus." Dr. Wathen holds that the increasing percentage of success under the improved methods in abdominal surgery justifies a

timely operation in the interest of both mother and child, and should have the preference over craniotomy. In the early operation 82 per cent. of children have been delivered alive. The success of the double operation has been remarkable. Of nineteen double operations, upon eight women, but three deaths have occurred; and upon forty-eight women a single operation has been performed, with but seven fatal cases. Dr. Wathen very justly holds that the performance of the operation in the future cannot be based upon the statistics of the past. They have been based upon cases of all classes, and into them enter many cases that were hopeless, because not timely. The operation should be performed as an operation of election, and if performed in time, the cases resulting fatally, under proper precautions, would be reduced to a very small per cent.

In discussion of the paper Dr. Yandell took exception to these deductions, because of the unreliability of statistics.

In reply, Dr. Wathen said, "Dr. Yandell is correct in his remarks concerning the unreliability of statistics, but he has shown how the statistics may be corrected. This has already been done, in this country, by Dr. Harris, of Philadelphia, and he has thus arrived about as near the truth as we usually do in capital operations. Therefore, instead of being insufficient data, as he claims, from which to draw logical conclusions, they are quite as ample as the data he claims to have based his conclusions upon concerning tetanus."

Dr. A. D. Price of Harrodsburg, the President elect, was at this time conducted to the platform, when he said:—

"Gentlemen, I thank you for the unexpected honor you have conferred upon me. Unsought, it comes a welcome gift from my professional brethren. I fully realize the responsibilities you have imposed upon me, and I shall endeavor to discharge them faithfully and impartially; at the same time it is expected that you, in the liberality of your hearts, will forgive much. It shall be my pleasure to uphold the interests of the medical profession. Hoping at another time to have something to say worthy of your attention, I beg to wish you, when the proceedings of this meeting are closed, a safe return to your homes and the duties which there await you."

Dr. Greenly next presented a paper on "Fasting." It possessed but little scientific interest.

The next paper presented was by Dr. M. F. Coomes, of Louisville, on Color-blindness, during the discussion of which Dr. Coomes took occasion to exhibit an instrument, consisting of a cylinder, whose sides were composed of eight different-colored glasses placed inside of another brass cylinder, in the side of which is an opening of the size of one of the pieces of glass composing the sides of the inner cylinder. These cylinders being placed, and a small lamp placed inside, the inner cylinder is made to revolve upon its axis, bringing the different-colored glasses over the open space between the flame and the eyes of the person whose perception is to be tested. The instrument is intended to take the place of the lantern test, which it does very admirably. In the discussion of the subject the doctor said, "Color-blindness may be congenital or acquired. The humors of the eyes of the color-blind do not differ in any manner from those of persons who possess the normal color sense."

The afternoon session was opened by a report on Dermatology, by Prof. L. P. Yandell. Prof. Yandell said, in introducing the subject, that John Hunter declared, a hundred years ago, that there were three classes of skin affections, one of which is cured by mercury, a second by sulphur, and the third the devil himself can't cure. One of the cogent reasons for the neglect shown toward these affections is the confounding confusion which is found in the nomenclature and classification of skin diseases. Having devoted special attention to the subject during a practice of ten years, and having mastered the subject, so far as library study would permit, he devoted a year to the study of skin affections in the European hospitals. He found, on his return, that his theoretical knowledge had increased; but, practically, he was as helpless as before. Driven to study the subject himself, he had gradually developed a system of practice which he has pursued with almost uniform success for a number of years. By this system he claims to have reduced the cure of skin diseases almost to a certainty. But, notwithstanding the fact that he had endeavored for the last ten years to disseminate and illustrate the nosology and etiology of these affections, he had been frequently accredited with acknowledging but three sources of disease, viz., malaria, scrofula, and syphilis.

Dr. Yandell asserts that he never has expressed nor entertained such a tripodal opinion. But he does maintain that while the manifestations of disease are numerous and varied, the causes of disease are few, and very generally comprehended by the following list: malaria, scrofula, the catarrhal poison, the specific poisons of contagious infections, the mineral and vegetable poisons, insufficient light and air, parasites and traumatism. Most conditions called disease are but symptoms of disease. Dr. Yandell maintained that the only curable contagious disease is syphilis, unless erysipelas, diphtheria and puerperal fever be added; but, he supplemented, very few of our patients are under favorable circumstances for recovery. "Many diseases," said he, "claimed to be incurable I claim to be curable entirely when the subject is placed under circumstances that favor recovery."

In a nutshell, Dr. Yandell believes most diseases due to the causes he has mentioned, and a large majority of them due to malaria and scrofula. The third class of skin affections referred to previously he believes to acknowledge an underlying scrofulous cause and an exciting or malarial cause. On this foundation his treatment is predicated, which consists of antiperiodics and tonics; in short, the treatment for consumption.

Dr. Yandell's paper elicited much interest and some discussion, which space does not permit.

Prof. J. M. Matthews, of this city, made some oral remarks on the subject of "Divulsion in Stricture of the Rectum."

Dr. Matthews said, "I beg to speak for a few moments on the subject of stricture of the

rectum and its treatment, and I shall take occasion to refer incidentally to the treatment by divulsion. This subject is of more importance than would appear at a glance. Few are aware of the number of cases that present themselves to the surgeon within a year. I do not know any disease that calls for surgical interference that is of more importance and deserves more careful consideration. It is one of the most harrassing afflictions that can affect a patient. Besides being one of the most painful, it is, as a rule, when it comes under the care of the surgeon, beyond the hope of any permanent cure. If, then, there is any operation that can be devised to mitigate, if not to radically cure this affection, we certainly ought to consider it. Cases of obstinate constipation not infrequently come under the care of the physician; and in these, not once in a hundred times is a local condition sought in order to explain it. I was glad, however, to hear the expression, a local manifestation of a constitutional disease. Although the consideration of the etiology is too great to begin upon in one discussion, yet, in a general way, the causes of stricture of the rectum may be enumerated in the order of their frequency, as follows, viz.: syphilis, cancer, traumatism."

Dr S. J. Rhodes, of South Carrolton, next read a paper on the subject of "Iodide of Potassium in Recurring attacks of Pneumonia." His illustrative cases were adapted to prove, as he claimed, the efficacy of the drug during the convalescence from an attack of pneumonia, as a prophylactic against subsequent attacks, and an unfavorable degeneration of the products left by the disease.

Dr. Ap. Morgan Vance read "some Practical Suggestions in the Treatment of Spinal Caries." His paper was well received. He also presented to the Society a case which he had operated upon for knock knees.

Dr. A. W. Johnson, of Danville, read a paper on "Carcinomatous Metamorphosis."

FRIDAY'S SESSION.

Dr. Lanaber, of Louisville, read an interesting paper on Cerebro-spinal Meningitis. Dr. Lanaber detailed several interesting cases, and spoke at some length on the subject of complications of the disease with pneumonia.

Dr. A. H. Kelch, of Louisville, made some observations upon obscure brain lesions. This paper, laying aside the anatomical grounds upon which the conclusions were based, maintained, that the choked disk, upon the subject of which there is a diversity of opinion, occurs as a result of those conditions of the brain which interfere with the circulation of the blood through the ophthalmic artery, between its origin between the nates and testes and its distribution at the cribriform plate of the sclerotica. Also, that the nervous manifestations produced by any adventitious product in the brain will depend entirely upon the seat of such product, and not its character. Let it be syphilitic, cancerous or tubercular in character; let it be due to traumatism from the rupture of an artery or due to any of the various causes that may produce pressure on the substance of cerebral ganglia on the cerebral substance.

The paper was discussed by Drs. L. P. Yandell, J. A. Octerlony, J. W. Holland and Von Dorehoff.

Dr. Reynolds exhibited several specimens of glass which had changed color by exposure to light, and demonstrated the defective quality of the glass ordinarily used for making spectacle lenses. He showed that commercial crown glass contains adulterating materials, sometimes iron, lead, or manganese. Such glass, on being exposed to the air, soon changes color, and ceases to be even an approximately correct refracting medium. He pointed out that optical glass is a more carefully prepared form of crown glass, the alkaline salt used being the borate of soda. He also demonstrated that commercial crown glass cannot be worked over so as to render it fit for optical use, and stated that the quantity of borax required to produce a good quality of optical crown glass, which shall be entirely achromatic, could never be accurately determined. The chief point of importance, however, being the necessity for very prolonged fusion at a uniform temperature, and a prolonged and, as nearly as possible, uniform reduction of temperature to the desired point of cooling. He then demonstrated, with an improved form of Snellen's phakometer, the perfectly unreliable quality of commercial lenses, showing both their want of symmetry and accuracy of gradation, according to either the English, German or French scales for grading lenses. His experiments were brilliant, and were applauded by the Society.

In the afternoon papers were read by Dr. A. M. Cartilage, of the City Hospital, on Acute Brominism; by Dr. Brandt on Tubular Diarrhœa.

About this time it was moved by Dr. L. P. Yandell, after some preliminary remarks, that a committee be appointed to express the sentiments of the Society as to the recent action of the 80 doctors representing the profession of the State of New York.

The committee was appointed, and reported through its Chairman, Dr. Octerlony, as follows:

WHEREAS, Resolutions have recently been adopted by the State Medical Association of another State, subsersive of the code of ethics of the American Medical Association.

Resolved, That the State Medical Society of Kentucky regard the code of ethics of the American Medical Association the best code now extant for the governance of honorable and scientific medical men, and that we hereby declare our firm and unfaltering adhesion to the principles of said code, and deprecate any change in it until such a change can be devised as can be clearly shown to be desirable and an improvement upon the code now in force.

Resolved, That our representatives at the approaching meeting of the American Medical Association are hereby instructed to give their votes and influence in favor of the code as it now stands.

Then, after a vote of thanks, including everybody and everything, the Society adjourned to meet in Louisville, on the first Wednesday in April, 1883.

Consultations.

"A single doctor, like a sculler, plies;
The patient lingers and by inches dies;
But two physicians, like a pair of oars,
Waft him with swiftness to the Stygian shores."

Prevention of Venereal Diseases.

From the *Archives of Dermatology* we note that the following Act, prepared by the American Public Health Association, is to be presented to the Legislature of Maryland:—

ARTICLE 1. Be it enacted by the General Assembly of Maryland, That any person who shall knowingly communicate, or be instrumental in communicating, by any direct or indirect means, a contagious disease, such as smallpox, scarlet fever, or venereal disease, shall be deemed guilty of a misdemeanor, and shall be subject, upon conviction in any of the Circuit Courts of the counties of this State, or in the Criminal Court of the city of Baltimore, to a punishment of six months' imprisonment in the House of Correction of Maryland.

ARTICLE 2. Be it further enacted, That if any person, being the owner or occupier of any house, room, or place within the limits of this State, having reasonable cause to believe any person to be affected with a contagious disease, induces or suffers such person to remain or be at that house, room, or place, he shall be deemed guilty of a misdemeanor, and on summary conviction in one of the Circuit Courts of the State, or in the Criminal Court of the city of Baltimore, shall be liable to a penalty not exceeding one hundred dollars, or, at the discretion of the Circuit Courts of the State, or of the Judge of the said Criminal Court, be imprisoned in the county jail of the county in which conviction takes place, or in the Baltimore city jail, for any term not exceeding six months.

ARTICLE 3. And be it further enacted, That the State Board, with the approval of the Governor, and the Health Board of the city of Baltimore, with the approval of the Mayor, shall have power to remove to a hospital or hospitals all persons suffering from contagious diseases, who, from failure to take proper precautions, imperil the health of the community.

ARTICLE 4. And be it further enacted, That this Act shall go into effect on the first day of June, eighteen hundred and eighty-two.

This sets a good example, that all of our States would do well to follow.

Compulsory Vaccination in Indiana.

From the *National Board of Health Bulletin*, we note that the following special rules concerning vaccination have been issued by the Indiana State Board of Health:—

1. After January 1st, 1882, no person, until they have been successfully vaccinated, shall be admitted into any public or private school or institution of learning within this State, either in the capacity of teacher or pupil, and all persons admitted therein shall present to the principal thereof the certificate of a reputable physician as to the fact of their being successfully vaccinated.

2. It shall be the duty of all unvaccinated persons within this State to be successfully vaccinated within sixty days from January 1st, 1882. And all unvaccinated persons coming into the State shall be required to be vaccinated within sixty days after coming into the State.

3. All children born within this State shall be successfully vaccinated within twelve months after birth. All vaccinations shall be with reliable bovine virus.

British and American Physicians in Paris.

With a view to promote social intercourse and maintain good fellowship between British and American physicians, a society has been formed, under the name of the "British and American Medical Society of Paris." Membership is limited to British subjects and citizens of the United States of America legally entitled to practice as physicians in Paris, and actually doing so. A certain number of dinners are appointed to be held annually; the first took place on February 1st. Among the members who form this society are Dr. McCarthy, Sir John Rose Cormack, Dr. Thomas Bishop, Dr. the Hon. Alan Herbert, Dr. Pratt, Dr. Marion Sims, Dr. Johnston, Dr. Faure-Miller, Dr. Jennings, Dr. Murray, Dr. Pepper, Dr. Rowlatt, and Dr. Loughnam, etc. The President for 1882 is Sir John Rose Cormack, and the Vice-President Dr. Bishop.

Hygienic Value of Electric Lights.

From the *British Medical Journal*, we note that *La Nature* summarizes a communication from Dr. Javal, who believes that the electric light is absolutely without danger to the sight, in consequence of the amount of division that can now be obtained in it. *L'Union Médicale* says, "The observations of Drs. Blasius and Hoppe, in a discussion which took place at a meeting of the Brunswick Society of Natural Sciences, are also noteworthy. These scientists have shown that illumination by the electric light deserves preference over all other methods in use, for the following reasons: 1. It does not pollute the air with deleterious gases or other unhealthy products. 2. It induces a greater visual unity than with daylight and gaslight. The conclusion adopted by the meeting was, that "the hygienic qualities of the electric light have not hitherto been appraised at their real value."

A New Medical College.

A new and apparently very liberal college, to be known as the "Illinois State University of Medicine," has been organized in Chicago. According to the Chicago *Medical Journal and Examiner*, its professorships will be unlimited, a new chair to be created for every worthy candidate, which will probably result in giving the title of "*Professor*" to every physician in Chicago.

Disinfection.

Dr. Arthur Hill Hassall writes to the *Lancet*, about the danger of conveying contagious diseases from one person to another through the agency of clinical thermometers, and suggests that physicians carry around with them a small phial containing a solution of permanganate of potash or carbolic acid, into which they should dip the thermometer after each use, and then thoroughly dry. Similar precautions should be used in the

case of throat brushes; and since it is almost impossible to ensure the thorough purification of sponges that have been used once, imbued with animal matter, more particularly in a state of decomposition, or which have become infected with bacteria, they ought on no account to be used for more than one operation.

D. Hayes Agnew Medical Association.

A number of physicians of Philadelphia have permanently organized the "D. Hayes Agnew Medical Association," by electing as officers for the current year: President, Dr. F. O. Nagle; Vice President, Dr. G. P. Oliver; Secretary, Treasurer and Librarian, Dr. G. Maxwell Christine. Among the objects of the Association are the circulation of medical books, pamphlets, essays and journals, and at the monthly meetings of the body discussion of subjects relative to the profession. The meetings are held on the evening of the first Tuesday in each month.

Hydrophobia.

From a daily cotemporary we note the following marvelous instance of the immense vitality of the toxic agent of rabies; when and where will it stop?

"Some ten days ago, a dog bit a cow. The cow, subsequently, showed signs of hydrophobia, and was killed. A youth, nineteen years of age, who washed the cow's leg after the animal was bitten, and who had a sore on one of his hands, now shows symptoms of hydrophobia."

Examination of Wines.

The *Medical Times and Gazette* says: From the report of the municipal laboratory of Paris, for the month of December, of 409 samples of wine which were purchased and analyzed, only 79 could be described as good, 145 are said to have been "passable," while 146 are pronounced as bad, and 89 as injurious.

OBITUARY NOTICES.

DR. JOHN OSBORN.

Dr. John Osborn, a well-known physician of New York, died at his residence, at No. 259 West Thirty-fourth street, on Friday, the 24th of March, from softening of the brain, in the sixty-fourth year of his age. Dr. Osborn was born in New York city in December, 1818, and was a lineal descendant from the Rev. Samuel Osborn, who was Rector of the first Episcopal church established in East Hampton, Mass, in 1713. Dr. Osborn's profession might be called hereditary, as his ancestry for several generations have been active medical practitioners. Dr. Samuel White Osborn was his father, and Dr. John Osborn, a leading physician of Middletown, Conn., his grandfather. His uncle, Dr. John C. Osborn, practiced medicine in New York, and his brother. William F. Osborn, is at present a member of the medical profession. Dr. Osborn's son, John Osborn, Jr., who died a few years ago, at the early age of 25, was also a member of the profession which four generations of his ancestors had followed. Dr. Osborn was educated at Columbia College, and was a graduate of the Class of '36. He immediately afterward entered the College of Physicians and Surgeons in New York, from which he was graduated in 1839. He has practiced his profession actively in New York since then, until within the last two years, when the disease which caused his death was first fixed upon him. For the last year he has been confined to his house. Dr. Osborn was a member of the New York County Medical Society, and of the Physicians' Mutual Aid Society of New York, at the time of his death.

DR. J. M. LEON.

Dr. J. M. Leon, a well-known physician, died at his residence, Thirty-fourth and Walnut streets, on the 24th ult., at the age of eighty-one years. He was born in France, and served as a surgeon in the armies of that country. In 1832 he came to Philadelphia, built up an extensive practice, and amassed a large fortune. About fifteen years ago he retired from active professional duties, and since then has been regarded as somewhat eccentric. The deceased gentleman's death was caused by pneumonia.

—Dr. William Gould, an old citizen of Buffalo, is dead. He was born in Cambria, Niagara county, N. Y., June 21st, 1811, and went to Buffalo when a young man. He was graduated at the Buffalo Medical College in 1850. The only public office he ever held was that of Health Physician. He was thoroughly conscientious in whatever work he undertook, and kind-hearted, charitable, and genial.

QUERIES AND REPLIES.

W. H. H.—The formula for Fehling's Solution:—

℞.	Cupri sulph.,		ʒij
	Sod. and pot. tart.,		ʒiss
	Liq. sodii,		fʒivss
	Aq. destil.,	q. s. ad.	fʒviiss.

A. G. M.—In relaxation of the Pelvic Symphyses, Prof Lusk, of New York, recommends a pair of strong breeches, carefully fitted to the thighs and hips of the patient, and made to buckle in front and lace behind, The apparatus is light, comfortable, and answers every requirement.

MARRIAGES.

MYERS—SMITH.—At Louisville, Ky., March 7th 1882, by Rev. J. C. Converse, J. Myers, M.D., of Reno, Ind., and Annie G. Smith, of Louisville.

PITNEY—BLACKMAN.—In Absecon, N.J., March 21st, 1882, by Rev. Allen H. Brown, Jonathan Kay Pitney, M.D., and Charlotte Amanda Blackman, of Port Republic, N. J.

DEATHS.

BURTON.—In Ludlow, Vt., March 20th, 1882, Dr. Putnam Burton, 76 years of age.

CATHCART.—In this city, on the evening of the 28th of March, 1882, Dr. Thomas Holmes Cathcart.

KENDERDINE.—In this city, on the 27th inst., Robert S. Kenderdine, M.D., aged fifty-one years.

MOORE.—Suddenly, at Germantown, Phila., on Saturday morning, March 25th, Thomas Moore, M.D.

PERRY.—In Brooklyn, N. Y., on Wednesday morning, March 29th, John Schoolcraft Perry, M.D., son of Amos S. and Sarah H. Perry, in the 34th year of his age.

SOLLIDAY.—At his residence, Sumneytown, Montgomery Co., Pa., Dr. Samuel Solliday.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

MALARIA.

BY SAMUEL PETERS, M.D.,

Of Cohoes, N. Y.

Read before the Union Medical Society of Saratoga, Washington and Warren Counties, February 21st, 1882.

It seems that the profession is just now waking up to the subject of malaria; and certainly it is high time, for the reason that its influences, dire and insidious, have been working, mostly unrecognized, for all time past. That there is any more now than heretofore, except possibly in some localities, from special causes, I do not believe. It exists now exactly as it did in all the years past; no more and no less. But, thank fortune, the medical profession is beginning to study it with that care and diligence that will result in nothing but good to the human race, not only in its therapeutic management, but in the hygienic measures calculated for its diminution. That it existed many years ago, as now, the writer is able to prove by the fact that he instructed his students that if they would learn well the signs and symptoms of malaria in the human system, and its treatment, they could not fail in becoming good physicians, because a large share of disease ordinarily met with was either solely caused or to some greater or less extent influenced by its insidious yet recognizable workings; and I find in a published record of my own, about fifteen years ago, the following remarks written on the subject of "lumbago":

"Whatever the nature of malaria may be, it is certain that it inhabits the bodies of a large proportion of the population, especially in some regions. It is also certain that it gives character to any disease that happens simultaneously to affect such a body, the same as syphilis, gout or lead does; that it sometimes, and often, so impresses a previous disease as to exercise a predominating influence, and must be neutralized before the disease can be cured; in fact, by so neutralizing it the disease of which it may be called a complication will yield of itself, or more properly speaking, by the powers of nature. To include this whole subject in one brief paper would, of course, be impossible. I may be allowed, therefore, to present some of the salient points involved, some of the more practical questions that are met with in our every-day experience, and leave the rest to be wrought out by our subsequent investigations. Surely our opportunities for observation are numerous, for everywhere the atmosphere is the ready bearer of this insidious poison. I say *everywhere*, because it is conceded that no region of any extent is altogether exempt. The north, south, east and west furnish vast fields for the easy generation of this subtile 'something;' and, indeed, it may probably be declared to be universal."

The writer's experience in the northern, western and southern States of this country enable him to express confidently such a belief. Twenty years ago, during our late rebellion, it is well known that in every part of the country which was occupied by our army our soldiers were severely affected by this cause. So much so that every disease and almost every injury was more or less influenced by it. Take a pneumonia, a dysentery, a typhoid fever or a bullet wound, and ten to one the call came, sooner or

later in the course of its treatment, for the free administration of remedies for malarial complications. Hertz utters this language, however, in the second volume of Ziemssen's Cyclopædia, which to me seems remarkable, viz: In England malaria is encountered but rarely, and is endemic only on the eastern coast and in some of the lowlands of the Thames," and adds, "Scotland and Ireland are free from it." I cannot but doubt the absolute correctness of this sweeping assertion, when over such an extended area the cause of miasmatic emanations, viz: decay of organized matter, must exist. However this may be, there can scarcely be a doubt that it exists, though much less concentrated, and hence not producing the severe but the milder effects in the human body, even in the countries included in this broad assertion. In further proof I will only add that Aitken and W. C. McLean, English writers on malarial diseases, mention no such immunity. The point I make in this part of my subject is that malarial influence is widespread, if not universal; and another point, that it existed for generations past precisely as it exists to-day.

A very important as well as practical question may be discussed at this point, namely, that of *mortality*. In this, as in many other medical questions, physicians disagree; some claiming that it often assumes a form that is speedily fatal, requiring only a few days' continuance to produce such a result; sweeping away the patient in a week or two. Others are of the opinion that ordinarily the poison of malaria is seldom fatal; that it may and does pervade the system for weeks and months, continuing its work but never increasing in intensity far enough to threaten life, unless the subject be in a particularly unfavorable state; even then only rendering it less resisting to the diseases already affecting it, and thus after a period, indirectly aiding the fatal result.

The writer, judging from his personal experience as well as the testimony of writers generally, is decidedly with the latter class in opinion, after watching with some degree of care the operation of miasma in the human economy, and continuing such observations in thousands of cases for the last thirty-seven years.

It is true that in the Pontine marshes, the Campagna of Rome, and some other similar localities fatal results may speedily supervene. Again, in other localities less pestiferous this toxic agent may induce complications capable of contributing to a fatal result; but ordinarily, and in a very large percentage of the cases, no such result is to be expected. Indeed, as a rule, it is comparatively harmless, only as it slowly leads on to a cachexia or perverted state of the whole organism. Even if appearing as a complication of a particular disease, its power, when recognized, is almost always easily neutralized with appropriate treatment mingled with the treatment for the original disease. The fashion, therefore (for I fear it is becoming such at the present day), of ascribing *malaria as a cause* in our severe, or protracted, or fatal cases, should be very carefully considered in the light of truth, which is the only light of science. Few, I have charity to believe, are willing to pronounce such a verdict merely to cover up the want of a proper analysis of the case and the true cause of death. Such a diagnosis may be expected among the irregular and uneducated, not among the devotees of learning and science. The point, therefore, which I note here is that, while malarial disease and complications are very common, it is by no means to be charged with an evil agency in everything.

Having spoken thus openly, and perhaps strongly, on the question of accuracy in diagnosis, it will certainly be proper to indicate the principal symptoms by which we may distinguish the presence of this toxic agent in the human system. This I shall proceed to do willingly enough, yet not without the fear that my brief paper cannot contain all that should be noted on this very important point, for this is really the *fons et origo* of success in treatment.

From the days of Celsus, and perhaps far more remotely, it has been known that *periodicity* is a prominent symptom, one that when well marked is extremely valuable as a diagnostic sign. And further it may be expected to present itself, not only in purely malarial disease, but also more or less distinctly in others in which it forms a complication. True, it may at times be very indistinct; yet careful observation will rarely fail of detecting something of its presence as a modifier of symptoms producing an approach at least toward exacerbations.

Nevertheless, this feature taken alone cannot always be relied on, as is well known. Other diseases, unconnected with malarial poisoning, often present sets of symptoms involving those of periodicity. Notably is this the fact in most brain affections, when, if this symptom be taken alone, the physician may be misled. It will generally be observed in the earlier stages of tubercular meningitis, and it may be often noticed in the severe inflammations of the auditory apparatus, or the frontal sinuses, or the orbit.

In such cases it is evident that great caution is

to be exercised, as a full course of treatment for malaria, especially with quinine, would result in injury. Fortunately we have other equally prominent and corroborating symptoms, one of which is *intermissions*, or notable remissions.

This symptom, like the other, though especially useful and deserving of full consideration, cannot be relied on singly. However, the two taken together furnish valuable evidence.

The *variations of temperature*, as determined so accurately by that valuable little instrument, the fever thermometer, deserve particular attention, especially the character of the rise, which is particularly sudden, and also the very high degree of elevation generally attained, often, and unlike most other affections, reaching 104, 105, 106, or even higher, the first day, as well as in subsequent exacerbations.

Pain in the back is another symptom almost invariably present, generally severe, and voluntarily spoken of by the patient, most frequently occupying the lumbar region, sometimes the dorsal, and sometimes the entire length of the spine. The writer is invariably particular to inquire for this symptom, and considers it a strong diagnostic sign.

It will be observed that I have not spoken of *chills*, which symptom, although of the utmost value as a sign, is so common in other affections that, to be of real significance, we must wait for a repetition at a period subsequent to an intermission. One or two such repetitions occuring at regular periods can be accounted as positive or almost positive evidence of the presence of malaria. One peculiarity in regard to chills is that they are apt to continue for some time after the temperature begins to rise, and a still more notable peculiarity is that the patient is readily chilled nearly all the time, when he moves in bed or is exposed in any way; even during the intermission he frequently seeks a warm room or more clothing. This fact, I think, should be impressed, because it will often alone settle our diagnosis.

I will now speak of a symptom which I think of exceptional value, and which I do not remember as having been referred to by writers, namely, *a moist wrist*. This is scarcely ever absent, and when taken with even one or two other symptoms spoken of, I cannot but believe it to be almost pathognomonic. This moisture has a peculiar sticky feel, and when detected I scarcely feel required to ask the patient another question, because I can describe his case to him as well as he can to me.

But I must not omit to mention another symptom, although my space is limited: A symptom, perhaps of all others the most significant, the most attracting in its meaning, the most reliable. I refer to *sweating*, or free perspiration during some part of each day. Gentlemen, the rule of my life has been to administer quinine in a very large percentage of the cases where this symptom was present, and it is present in our malarious region in many diseases not ordinarily considered malarious. I entertain no doubt, after an extended line of observation, that this rule may safely be followed, always excepting, of course, the cases that do not present a few, at least, of the other symptoms of the presence of malaria.

I am aware that this is a digression, but I have made it in order to more thoroughly impress the rule spoken of. Of course it requires the careful analysis of the careful physician; but it surely is worthy of attention.

A word or two may be spoken in regard to the tongue. It presents an appearance that is quite significant, but hard, if not impossible, to describe. This organ, taken as a whole, is slightly paler than natural, always moist, and evenly covered with a light colored, velvety coat. It is quite recognizable, and once seen always remembered.

A *cough*, sometimes severe, sometimes slight, generally accompanies malarial infection, and many such a cough cannot be broken up unless treated with anti-malarial remedies.

Having now mentioned some or most of the diagnostic symptoms (and this is all of this part of our subject we proposed to do) a brief recapitulation may not be out of place.

To enumerate, then, the symptoms as spoken of and in their order: We have periodicity, intermissions, extremes of temperature, pain in the back, chills, moist wrist, sweating, the peculiarity of the tongue and cough. These are mentioned in the order of their significance, except the perspiration, which is most to be relied on provided it be supported by a few, more or less, of the other symptoms.

It frequently happens that all the subjective symptoms are not present, yet two or more of them are generally sufficient, provided free perspiration, or at least a coolish, damp skin, appearing during some portions of each day, be one of them. With this, and the exclusion of possible exceptions already noted, we are tolerably safe in considering our diagnosis established, and in commencing proper anti-malarial treatment. However, in spite of all due caution, there will occur cases in which we have reason to feel a doubt. In such cases a few small, very small, trial doses, carefully watched, will settle the question on

one side or the other. The skin will begin to open and the intensity of the symptoms abate, or, on the other hand, the heat will be increased or the symptoms aggravated, or both, thus settling the question which before was conjecture.

Before proceeding to a very brief consideration of the treatment, I wish to call attention to a remark in the excellent work of Dr. Frederick L. Roberts on Practice of Medicine, with which I can scarcely agree, namely, that "young children are least subject to malaria." In my own practice I find many cases among children; fully equal to the ratio they bear to the population. Even young infants are by no means exempt, such being more subject than adults to aggravations of the cough named above as a diagnostic symptom. Many a little sufferer with labored breathing and severe cough is rapidly relieved with small doses of quinine.

It is not proposed in this paper to enter into a general discussion of the treatment, but to allude to only a few points.

A word may be spoken here in regard to drinking water, which, as is well known, is a common carrier of this and other poisons. For good reasons we have learned that wells and springs, especially the former, are common sources of malaria, because most of them contain percolations from the soil or surface of the ground, and of necessity the products of decaying matter. In our own city I find this especially true, and hence I am free to discourage the use of such water. Hydrant water is far preferable, and the reason why it is so, probably, is that it has more motion, more friction among its own particles, never lying so still and dormant as in wells. Why may not friction, constant agitation, destroy the spores, or whatever the substance is, of malarial poison? Large reservoirs for cities' supply, wherein the water lays dormant, never in activity only while flowing through the pipes, are not desirable. The smaller the reservoirs the better. The Holly system of water supply may and probably will be found preferable to others. Much might be said on this important subject, but time will not permit. I will merely give a case in point. A family consisting of four persons, by the name of Winterbottom, in our city, was taken with dysentery, only one of its members first. I found this and one other were particular to use the water from a well, not far away; the other two used hydrant water. In a somewhat jocular mood I said to the mother that I would assume to be a prophet! that those who used the well water would suffer most. The result proved my prediction true. The two who drank the well water were very sick; one died. The other two had the disease, but in a much milder form.

I shall occupy my remaining time in speaking of the use of quinine and iodide of potassium as the principal remedies; and arsenic and eucalyptus globulus as remedies in the cachexia of malaria and quinia.

For more than two hundred years quinine has held the sway as the remedy *par excellence* in the treatment of malarial diseases and complications. Little need now be said in regard to it, after the researches of Binz, Bartholow, H. C. Wood and a host of others. In the mode of administration, however, there is some disagreement. Without giving the views of various writers, I wish simply to offer a point or two in my own experience. I find that I give almost invariably small doses; compared with the doses recommended by most others, they are *very* small. Seldom do the doses in my prescriptions exceed one half to two grains, and never, except in rare instances, is it found necessary to go beyond this amount; and during a general practice of many years this has been found amply sufficient. Indeed, ten to twenty grains, or even less, are, in the majority of instances, all that is desired for each case. I am unable to elucidate this, unless I am correct in the belief that in the administration of large doses much of it passes out of the stomach, and meeting with the natural alkalinity of the intestinal secretions, passes off unabsorbed and wasted. Even minute doses are often successful; and how can the fact be explained in any other way? It may, not therefore, be derogatory for a man with many gray hairs to recommend a careful consideration of this point. True, there are cases which require heroic doses, but in my experience they are few. Another explanation may possibly be, that I invariably administer the dose *every four hours*, never less or more. According to Bartholow, Binz and others, about five hours are required for the full effect of a dose to be reached, hence, to administer a dose, for instance, every two hours, or every eight hours, is folly, to say the least; the one exercises a cumulative influence, the other is partially lost. I wish to make every word a point in this matter, because, besides appearing reasonable, it has stood the careful test of many years.

Another point I cannot forbear alluding to is this: How long should quinine be administered to obtain its full anti-malarial effects? I answer forty-eight to seventy-two hours. At the end of this time all the good effects of the remedy may not be fully apparent, but I almost invariably stop its administration, and wait for the result, say twenty-

four hours, when it will generally be found to have accomplished its purpose. If not, it can be resumed for another like period. This is, however, seldom required. If it be not considered egotistical, I would make every word of this also a point for special consideration, being fully satisfied of its general truth.

Again, in regard to the long continuance of the use of quinine, something may properly be said. When this remedy is continued, even in moderate doses, say ten or twelve grains a day for several days, perhaps we may name one or two weeks, or often less, there begins in the patient what may properly be called *quinine cachexia.* The mere mention of this term, quinine cachexia, may convey a slight shock to the mind of the profession, and if so, I must face the responsibility, whatever the result. By the term I do not mean the fullness of the head, the ringing in the ears, the staggering gait, etc., produced by a few full doses, or by a single large dose, but the condition which may be called toxic, and characterized by a far different train of phenomena. These are, taken as a whole, very like the poisonous effects of malaria itself, that is, like intermitting fever. The symptoms of each are so similar that it is easy to be misled unless the history of the case be taken carefully into consideration, the quantity of quinine ingested, and the length of time it has been taken, etc. I have never seen its continued use fail of producing the state spoken of, and, indeed, such a condition has long been recognized. When it is once reached I am well convinced that quinia has lost much if not all of its salutary properties, and that the sooner its use is abandoned the better. The state for which it was rightfully administered, viz: the injurious presence of malaria, is fully remedied, generally speaking, and the toxic effects of the remedy substituted. With this belief I am convinced that many of the cases of the so-called "obstinate intermittents" are nothing more or less than quinine cachexia. I submit these studies to the careful and unprejudiced attention of the profession, in order that the truth or falsity of my position may be proved. The writer has met with many cases in point, which we cannot here relate, for want of time, and which were cured by simply withdrawing the quinine, and perhaps administering drop doses of Fowler's solution, and waiting a few days or weeks for the removal of the quinine saturation. For the same state iodide of potassium is an excellent remedy, given in small doses, or eucalyptus globulus either, for some length of time. The arsenic, in my experience, is generally preferable.

To avoid the cachexia, I am in the habit of giving the quinine till its full effects are obtained, then continuing treatment with the iodide, if necessary. I believe it was first recommended by Dr. Nonodnitschanski, in the form of the clear tincture of iodine, administered in water, and its good effects have been tested and confirmed by others. See *Braithwaite's Retrospect*, part 83, page 225.

LACERATION OF CERVIX UTERI; ETIOLOGY, PREVENTIVE MEASURES, TREATMENT AND RESULTS.

Read before the Northern Medical Society of Phila.,

BY E. E. MONTGOMERY, M.D.

Our knowledge of the importance of this lesion and the operation for its relief comes from Emmet, though the lesion was given as a cause for sterility by Gardner, in 1856, in his work upon that subject.

Emmet performed his first operation in November, 1862; although he performed it a number of times in the next seven years, he published no account, until in February, 1869, when he read a paper before the New York County Medical Society, on the surgery of the cervix. In this publication he was preceded a few months by a paper from M. A. Pallen, describing practically the same operation, though unaware of Dr. Emmet's work.

The lesion and operation, however, made but little impression upon the general profession until a second paper by Dr. Emmet, in 1874. Since the latter date it has been extensively performed, and is now probably recognized as the most frequent gynæcological lesion and the one most demanding relief.

Authors differ greatly as to its frequency. Emmet found it in 32.80 per cent. of the women who had borne children, applying to him for relief of uterine disorders. Goodell and Mundé 17 per cent.: Pallen 45 per cent. My investigations in the Philadelphia Hospital lead me to believe that in nearly every primipara the cervix is fissured to a greater or less depth. That under favorable circumstances, where the fissure is slight and the vagina kept clean, the greater number heal without deleterious influences, but many continue unclosed, to aggravate and render miserable the future of the patient.

As to the site of the lesion, Pallen found that out of every one hundred cases 80 would present a tear upon the left side, 15 bilateral, and 5 upon the right. Emmet also found it upon the left side most frequently. Goode l, in one hun-

dred and thirteen cases, found the tear bilateral in ninety. In forty cases in which I have noted the seat of lesion, twenty-six were bilateral, with, in the majority of cases, the deeper cleft upon the left side, five of which presented a third posterior cleft, eleven presented a left-sided cleft alone, and three a right.

We can readily comprehend why the lesion should occur more frequently to the left, when we remember that the bi-mastoid diameter, in the greater number of labors, presents to the left side.

The frequency of the lesion is attributed to the use of forceps before the uterus is fully dilated, early rupture of membranes, failing to separate adherent membranes from the cervix.

One would naturally suppose that rapid labor would be an important factor in its production, but those having the largest experience have found it occurs almost entirely as a result of protracted labor. Rapid labor only occurs when the organs are in such a condition as to be able to properly discharge their functions. Any cause tending to protract the labor will increase the danger of producing this lesion, and hence may be considered a cause.

This subject has been well discussed by Pallen, in the *British Medical Journal* for the present year. In rapid contractions, where the placenta is attached at one side of the uterus, the muscular fibre being weakened at the site of implantation, causes a sigmoid wave of expulsive force directed away from the centre of the pelvic planes, or centre of the external os. As a result of this misdirected force, a segment of the cervix becomes folded over the advancing head, and becomes lacerated, because it is below the line of expulsive force. In such cases, the tearing begins within and extends toward the os; while ordinarily it begins at the os and tears toward the uterine tissue. It is likely to occur whenever, from any cause, as irregular pelvis or malposition of child, the symmetry of contractions be diverted into lines of expulsion away from the centre of exit, and the head be driven, anteriorly, posteriorly, or laterally, to form a capsule of the cervical segment, with production of perivascular ecchymosis, rupture of capillaries, œdema and bruising of tissue, by impinging against the pelvic walls. These conditions impair the elasticity and distensibility of the cervix. One of the most frequent causes is the scleremic state following inflammation or congestion, a result of the hyperplasia. In this condition the parts undergo shrinking, atrophy, and induration of the connective tissue, with agglutination of the muscular striæ, rendering the whole substance hard, inelastic, and friable. Such a state renders the uterus slow to dilate, and it exhausts itself by repeated efforts at expulsion. The jamming of the enveloping segment against the pelvic walls bruises the already inelastic, non-distensible tissue, and increases the tendency to rupture. The osseous structures too small, or the child's head too large, deformities existing which render necessary the application of forceps, the dragging of the child through a bruised and exhausted cervix, necessarily causes tearing. It may also occur in version and head-last deliveries.

Even though the channels of exit be normal, but the uterus inert, from an excessive amount of liquor amnii, causing the power of the contractions to be lost, from being diffused over too large a surface, a failure of elasticity, or sort of paralysis, will ensue; and though the head be disengaged without accident, the shoulders are almost certain to produce laceration. Here, unless the accoucheur recognizes the condition, and by judicious and skillful management rapidly completes the labor, the accident is almost unavoidable. If, however, proper hydrostatic dilatation be followed by version or the use of the forceps, the labor would be terminated before paresis, œdema or ecchymosis ensued, and, consequently, save the woman serious injury.

When it does occur, nothing short of surgical skill rescues her from future ill health, or, perhaps, death from immediate hemorrhage or septic surgical fever. These lesions do not recover of themselves, though the majority of obstetric writers do not consider them of much importance. The laceration may, and frequently does, occur when the physician's hand is thrust into the uterus, in the operation of version. Emmet says it may result from criminal abortion.

How are we to determine that the lesion has occurred? We are not able positively to say it has occurred until after delivery. But in roomy pelves it may be suspected when there is a sudden bloody bathing of the vulva or child's head; also, when the head has been impinging against a hardened, inelastic cervix, and suddenly passes through it, as illustrated by the following case: Mrs. —, the wife of a physician, had suffered from uræmic symptoms for a week; was seen at 9 A M., November 2d, 1880, when she complained of pains of an intermittent character which had distracted her rest the greater part of the night; the uterus was dilated to admit the finger; the vertex presented with the left occiput anterior. She was given a rectal injection of forty drops of tr. opii. During the day there was a bloody dis-

charge and severe pains, but os remained undilated. Given morphiæ sulph., gr. $\frac{1}{8}$, hypodermically. At 1 A.M., the 3d, os still undilated; at 4 A.M. wa called to find child delivered. Her husband informed me there were but two or three expulsive pains. The child was quite small, feeble, and died the following day. Her health was very slow in becoming reëstablished. A few months later the cervix was found to be lacerated bilaterally and through the posterior lip.

The symptom which causes us most strongly to suspect laceration is hemorrhage. If we find bleeding persists after the uterus has contracted, and the perineum and vestibule are untorn, we should make it a rule to assure ourselves by ocular inspection of the seat.

It is true, the finger will indicate the torn cervix, but should there be any doubt, there should be no hesitancy in placing her in a semi-prone position, retracting the perineum with Sim's speculum, cleansing the vagina of clots, and seeing the point from which the bleeding occurs. Supposing we find a rupture of the cervix; what is to be done?

Certainly good surgery would teach us to place the parts in such relation that the normal condition would be restored, and it becomes a question whether more than rest is needed to bring this about. In cases of slight laceration, union is probable, but when we remember the enlarged state of the organ, its subsequent process of involution, and that the wounded surfaces are constantly bathed with lochia, we are not surprised that in the majority of cases of severe rupture union does not take place.

The better plan would be that recommended and first practiced by M. A. Pallen, closing by wire sutures. All the conditions are favorable to its immediate performance—the vagina and vulva well dilated, the uterus easily drawn down. The sutures should be introduced and brought out a full half inch or more from the margin of the rent, remembering that we are dealing with greatly exaggerated tissue, which rapidly undergoes a retrograde process and consequently requires a deeper hold. The sutures should be twisted and cut half an inch long. The parts should be carefully watched subsequently, and if any of the wires show indications of becoming loose, they should be tightened by twisting. The sutures may remain two weeks. An antiseptic injection should be used several times daily during convalescence.

The advantages in performing the operation at once are, that it arrests hemorrhage, decreases the danger of septic fever, promotes involution, precludes the necessity of a secondary operation, and saves the patient a life of invalidism and the expense of future treatment.

When a deep laceration is allowed to remain unstitched, it will sometimes become closed, but more frequently union fails to take place. As a result of the fractured surface, or possibly the absorption of septic matter, a sort of paralysis of the capillaries occurs; the process of involution is arrested, the uterus remains large, its weight causes it to settle further down in the vagina, or possibly become retroverted, increasing the derangement of circulation. The traction upon the lips by the vagina separates them and is still further increased by pressure upon the posterior vaginal wall or floor of the pelvis. The constant motion to which the organ is subject, in respiration and exercise, breaks the granulations and keeps up the irritation.

When a woman who has had one or more children complains of leucorrhœa, menorrhagia, of greater or less degree, intercostal neuralgia, hemicrania, pains in either iliac fossa or in the back, with vesical or rectal symptoms, we have a cervical lesion, and as this is the most frequent lesion—of the cervix—in the mother, we are justified in suspecting its existence, particularly when the abdomen is free from tenderness. We can only arrive at a certain diagnosis, however, by an examination.

The convalescence of such a patient may be much retarded, having what is known as "a slow getting up," suffering at once from the symptoms we have enumerated. Others enjoy good health until lactation ceases, and the ovaries reassert themselves, when the woman finds herself an invalid.

Menorrhagia, though frequent, is not a constant symptom. In some cases the menstrual flow is diminished, and may even be absent. The cervix is found patulous, so that the finger readily enters the canal. The surfaces may be simply abraded, inflamed, angry looking, lying in contact, or widely separated, the lips hard, from inflammatory exudation, the mucous membrane everted, studded with mucous cysts and covered with granulations, or the clefts have healed over, and are the seat of cicatricial deposits.

It is sometimes difficult to determine the presence of laceration. The clefts may be completely filled with hard, dense tissue, having the feel of cartilage, the cervix larger at the extremity than above, and with its antero-posterior diameter greatly increased. Others are seen with

the cervix greatly hypertrophied, dense, covered with exuberant granulations, that bleed upon the slightest touch. Such a case may be readily mistaken for cancer.

In the spring of 1879 I was called to see Mrs. S., aged about 40, who had suffered from uterine disorder for some months; for the last three weeks she had had a continuous bloody discharge and shooting pains through the pelvis. She had lost flesh and appetite; the uterus was nodular, covered with exuberant, easily broken granulations, that bled when touched. The discharge was attended with an offensive odor. I had but little hesitancy in pronouncing it a malignant condition. Imagine my surprise, then, when it healed completely under applications of chromic acid alternated with glycerole of tannin, and disclosed five clefts.

The vaginal portion of the cervix has much to do with the maintenance of the uterus in its relative position to the other pelvic organs. Any laceration must increase the tendency to displacement. Retroversion is probably the most frequent. A peculiar form of anteflexion is sometimes seen confined to the anterior segment, which is hypertrophied and elongated, while the posterior is normal in size, or atrophied. If the laceration be one sided there is less eversion of the mucous membrane, but the uterus resting upon a sort of tripod, as the torn surfaces separate, produces a partial obliquity, by crowding the cervix to the uninjured side. Cellulitis has a similar effect by shortening the broad ligament.

Cellulitis is the most frequent complication, and is almost sure to occur when the lesion extends above the vaginal portion. Slight anterior and posterior lacerations are of but little significance, as there is but slight tendency to separation. They usually heal during convalescence, but a deep anterior sometimes extends into the bladder. The vaginal portion may close, leaving a vesico-uterine fistula.

These cases were formerly treated by caustics, as nitrate of silver, caustic potash, and the acids; by the application of the actual cautery, or amputation of the cervix; methods of treatment that resulted in the increase of cicatricial tissue and aggravated the reflex symptoms by the pressure upon the terminal fibres of the uterine nerves. The object of treatment should be, as far as possible, the restoration of the normal condition. This can only be done by freshening the surfaces and keeping them in apposition.

Some preparatory treatment is frequently necessary, particularly where there are evidences of former cellulitis or pelvic peritonitis, present inflammation of the cervix, or extensive eversion of the mucous membrane with cystic degeneration. Emmet expressly states the necessity of postponing the operation until all acute inflammatory symptoms are removed. The operation should not be done after a cellulitis or peritonitis, so long as any tenderness is present.

In performing the operation the patient is usually placed upon her left side, and the perineum retracted with a Sims speculum. Where the uterus is very movable, and vagina large, it may be done with the patient upon her back; the uterus is drawn down by a tenaculum, or volsella forceps, and transfixed from before backward by a curved needle bearing a strong silk thread. This thread is hooked down from the cervical canal, cut, and the ends tied, giving a handle for each lip. The tourniquet is now applied well above the lacerated surfaces. It may consist of a watch-spring arrangement, as used by Dr. Emmet, an ordinary wire ecraseur, or a flexible metal catheter with the end removed and a strong loop of thread passed through it, which is placed over the cervix and drawn tight, the ends tied around the rings of the catheter. I use the tourniquet in all cases, as it renders the operation bloodless, hence more agreeable and expeditious. The surfaces are now separated, and in a double tear freshened on each side, from one lip to the other, leaving a strip of mucous membrane in the centre of each, which forms the future cervical canal. This undenuded portion on each lip should correspond with that upon the opposite, and should widen toward the extremity, so as to present a trumpet shape. Great care must be observed in denudation, to remove all cicatrical tissue from the angle of the cleft. Should a wedge-shaped piece be allowed to remain, greater traction is made upon the sutures when the parts are approximated, and this mass, by pressure, arrests the circulation. Should union take place, its pressure upon the nerves included in its structure may cause reflex neuralgia.

In cases of long standing, where there is much cystic degeneration, and the lips are hypertrophied, everted, and convex, it is necessary to remove a large portion of tissue, so that the edges may be properly turned in. The cervix is sometimes lacerated in three or four places; were we to freshen each cleft, and bring them together separately, the result would most probably be failure, as the traction in opposite directions would cause the sutures to cut out. It is better to join two clefts by removing the segment between them.

In drawing down the uterus we must be gov erned by its movability. The lower surface should be freshened first, as then it will not be obscured by blood running over it. The portion to be removed is hooked up by a small tenaculum and kept on the stretch while it is being removed, which should be done by a single strip from one lip to the other. The denudation may be done with either scissors or scalpel. With either the surfaces should be made perfectly smooth and uniform in extent, the object being to bring about union by the first intention, as any granulation must result in cicatricial tissue.

In old cases the introduction of sutures is often quite difficult. The best needle for this purpose is one about an inch in length, slightly curved at the point and beveled at one side. It should be threaded with a silk loop held by a half knot. The wire suture is hooked into this loop. The first suture is introduced near the angle of the cleft; the others three lines apart, entered and brought out three lines from the margin of the freshened surfaces. The parts are cleared of foreign substances and the sutures twisted, observing care to have the freshened surfaces well covered or turned in. The sutures, cut an inch long and turned back, will give no trouble. They may be secured by shot, but are more likely to cut, leaving a ragged surface; also, more difficult to remove.

The patient should be kept in a recumbent position for two weeks. The bowels need not be constipated but should be evacuated and the urine voided upon a bed pan. After micturition a few syringefuls of warm water should be thrown into the vagina, to dilute any urine that may have passed into it. Antiseptic injections should be used daily after the first forty-eight hours. The sutures are generally removed on the seventh or eighth day, and care should be exercised not to separate the surfaces.

The patient is placed upon her left side, the cervix brought into view by Sims' speculum, the lower portion of the loop cut, and traction made downward. In this way the loop binds together the parts until it is completely withdrawn; if cut above it would separate them.

She should remain in bed a full week subsequent to the removal of the sutures. This rest promotes the union, prevents the danger of cellulitis, and helps decrease the size of the uterus.

It is necessary to exercise some caution as to what result we promise our patient; for this operation, though not a serious one, is not absolutely free from danger. Emmet has lost two cases, Dr. Hunter, of New York, one; they died from cellulitis or peritonitis. It does not always afford the relief we expect from it. It has been my own experience to have a patient suffer just as severely after a successful operation as before, much to our mutual disgust. We can, however, in all uncomplicated cases, promise complete relief. In cases of retroflexion and version it would be necessary to follow the operation by the use of a pessary, the comfortable use of which the operation greatly promotes.

It is often asked, "What effect will the operation have upon subsequent parturition?" If the cicatricial tissue is completely removed, and union secured by first intention, I cannot see why there should be any difficulty.

The last number of the *American Journal of Obstetrics* reports eight cases in which labor subsequent to the operation had not been attended by laceration.

Hospital Reports.

MEDICO-CHIRURGICAL COLLEGE.

SERVICE OF F. LE SIEURE WEIR, M.D.,
Clinical Professor of Dermatology.

(Reported by Dr. H. B. Nightingale, Chief of Clinic.)

Gentlemen:—Our clinical material being unusually abundant to-day, I shall have the opportunity of showing you cases illustrating several varieties of skin disease which I had occasion to mention in recent didactic lectures. Most of the cases are such as are met with constantly, and such being the case it behooves you to be familiar with them. The first case, which will now be brought in, is somewhat more extensive than is usually seen, and will give you an excellent idea of the disease.

Syphiloderma (tuberculosum).

Case 1.—This woman is an American, married, and 33 years of age. She tells us she was perfectly healthy up to five years ago, at which time she had been married to her present husband for one year, he being her second. At the time mentioned she noticed a small spot upon the forehead, which quickly pustulated. It was very persistent, and at last she thought to try the effect of inoculating herself elsewhere with the pus, to "see what it would do." She found out; and in doing so unconsciously settled the diagnosis. The place chosen was the shoulder, directly over the acromion process. The inoculated spot shortly gave rise to similar ones, all in the immediate locality. These tubercles, for such they are, have been present ever since, occasionally dying away for a few weeks. You here see the full-blown tubercles, while near them are others in their very incipiency; and somewhat removed are the old cicatrices. Each is coppery in color at the base, with intermingled erythema. The case is plainly syphilitic in nature. If more evidence is wanted to prove this, I may mention the presence of nocturnal pains in the bones, marked alopecia, sore gums, and a generally degen-

erated system. There is no history obtainable of a primary sore at any time. The tubercles are, as you see, covered over in part by dark scabs, and have a hard, inflamed base. Can we do anything for this? Certainly we can. To begin with, we will give her five grains of potassium iodide, with one twenty-fourth of a grain of corrosive sublimate, in half an ounce of cinnamon water, three times a day, after meals. She will take this for, say two weeks, after which she will be put on one-quarter grain doses of the proto-iodide of mercury, taken thrice daily, in pill. A proper interval, however, must be allowed between the two medicines, for when they are given together biniodide and metallic mercury are the result. Locally, an ointment composed of ung. hydg. nit., ʒ iij to ung. petrolei, ʒ v, will be used about twice daily. This will be followed by a soothing ointment of benzoated oxide of zinc, containing a few drops of carbolic acid. Good results may be expected from this, and if we could keep her long enough she would obtain permanent relief; but, like all such patients, as soon as the sores heal she will leave us.

Psoriasis.

Case 2 —Miss C., American, 22 years of age. This young lady has been sent here by a medical gentleman, for advice. The case shows us a number of white or pearl colored patches, situated mostly in the neighborhood of the joints, and having a tendency to extend downward toward the hands and feet. It is quite thick here about the elbow, and being well marked, you can see the scales piled up, one above another. I would like you to observe the shape of the patches, it being one means of determining the variety of psoriasis, for that is the disease; and also the size, as another point of diagnosis. The patient states that she has had the difficulty since childhood, but that during the summer months it nearly disappears. There is no itching to speak of. Her general health is good, and the menstrual functions are performed normally, while the stomach, notwithstanding the pouring down of a good deal of medicine, remains in good condition.

We have made out the disease but not the variety. Of the latter there are a great many—far more, in fact, than there is any use for—and they greatly confuse the student. I will refer you to the text books for their description, and only mention the variety known as *nummularis*, under which this case is classed. It is so named from the patches being about the size and shape of a coin. In the present case they are about the size of a half dollar. It is a disease utterly devoid of discharge of any kind, and is, therefore, properly classed under the squamous group. Pathologically, psoriasis, otherwise known as lepra vulgaris, consists of hyperæmia of the cutis, together with hypertrophy of the papillæ and excessive cell proliferation.

The patient being of a lymphatic temperament, as are a majority of the subjects of the affection, we will place her on cod-liver oil, giving a dessertspoonful three times daily, after meals, in emulsion. The Doctor has tried chrysophanic acid with a negative result. After awhile arsenic may be given here to advantage, I think, and the most desirable form is the solid, inasmuch as Fowler's solution is too varying in strength. Locally the treatment must be judicious, for harm may easily be wrought, owing to the sensitiveness of the skin, more especially in the young. She shall be ordered a bath every night, in which from two to four ounces of sodium bicarbonate are dissolved. After remaining in for not over ten or fifteen minutes she shall be dried and thoroughly anointed with olive oil or cosmoline. This will result in softening the skin and loosening the scales. Until the scales are got rid of, no direct medication will be used, for it would not reach the seat of the disease. I think we may venture upon slight stimulation then, and will, therefore, advise the Doctor to use something like the following:—

℞. Ung. hydrarg. nit., ʒ iij
Ung. petrolei., ʒ j
Ol. olivæ, fʒ iiss
Ol. cad., fʒ j. M.
Ft. ung.
Sig.—Apply twice daily.

Eczema.

Case 3.—This man, D. M. aged 70 years, Irish by birth, is also sent by a physician. He has had an eczema of the palmar surface of the hands for about eight months, and if you examine, you will see that extending in numerous directions are large cracks, which bleed when irritated by the movements of the muscles. Surrounding the cracks the epidermis is engorged, but evidently he is much better than he was some weeks or months ago. The man's occupation is that of a dyer, and the contact of the parts with the various dyes has given rise to the disease. There are present all the symptoms which ordinarily accompany this affection, such as itching, burning, etc., together with moisture, though the latter is not very prominent now, except in the immediate neighborhood of the fissures. The presence of the fissures determines the variety, and we therefore call it eczema fissum. No treatment other than for the cracks is desired, as it is doing well enough otherwise. We will, therefore, apply pure carbolic acid to the sides of the fissures, by means of a smooth piece of wood, and ask the Doctor to repeat this once or twice, weekly, as long as necessary. A very few will suffice, however. In addition, he shall have an ointment composed of—

℞. Hydrarg. chl. mit., ʒ ss
Ung. picis., ʒ iij
Ung. petrolei, ʒ ss. M.

Sycosis.

Case 4.—A. H., aged 30 years. This young man presents himself here to day with the state of affairs which you here see. The whole surface wherever there is beard is hot, red, swollen and tense, with pustules in abundance. He has persistently shaved the parts, which has only made matters worse. Each pustule is pierced by a hair, and this is to be borne in mind, for it is one of the diagnostic points. His occupation is that of an engineer, and the sudden transition from the hot air of the engine room to the cold air without has probably been the cause. This is strengthened by his evidently anæmic condi-

tion. How do we distinguish between this affection, known as sycosis, and the parasitic affection of the same name? In a recent didactic lecture I told you that it were better to call simple inflammation of the hair follicles sycosis, and a similar disease, caused by a vegetable parasite, tinea sycosis. The latter is the only disease with which it is liable to be confounded, and it shows us the eruption occurring at points not covered by hair; it does not affect the upper lip; and lastly, by means of the microscope we can detect the fungus. In the present case you see that the upper lip has not escaped, that each pustule in this situation is pierced by a hair, this being the only unshaven part. We will first give him a saline aperient and put him on tincture ferri chlor. in fifteen drop doses three times daily, in water. Locally, warm poulticing, followed by a soothing ointment of oxide of zinc or a lotion of lead water and laudanum. I do not much like the plan of laying open the pustules and tubercles, unless the case is a very severe one and does not take kindly to medication. The case before us is not one for an operation of this kind. He will be directed to let his beard grow, but keep it clipped close. Epilation does harm in these cases.

Herpes Zoster.

Case 5.—J. S., aged 6 years. This little boy is brought to us by his mother, who wants to know what is the matter with his side. Upon examination we find a small number of minute vesicles seated upon a somewhat inflamed base, and involving not quite one-half the body from the spinal column to the median line. The vesicles here follow the course of the cutaneous nerves, which is one of the peculiarities of the disease. It is a case of shingles, or herpes zoster. Being a simple case it needs no special treatment. We will simply give him a dusting powder of subnitrate of bismuth or oleate of zinc, and have his mother protect the parts from contact with the clothing by a piece of soft muslin. He will be well in a few days.

Tinea Versicolor.

Case 6.—W. G., aged 17 years. This young man has an affection of the skin which is very instructive. The whole front of the body is covered with brownish yellow staining, apparently from the neck to the pubis, and the back is not much better. The discoloration also extends down the arms as far as the hands, where it takes on the appearance of little erythematous points or spots. By passing the finger over the surface you see that it is uneven and rough, and that the parts have a greasy feel. The disease has existed for two years, and first began as a small yellow spot at the epigastrium, which gradually spread until it has assumed the proportions which you now see. He says that it itches very much, and that when warm in bed this is worse. No doubt it is.

It is a case of tinea versicolor, or chloasma, as it was formerly called. It is due to the presence and growth of a vegetable parasite upon the epidermis, known as the *microsporon furfurans*. There is no danger of contagion, for its activity in this respect is very feeble. The copper color of the syphiloderm is the only disease liable to be confounded with it, and there you have the history, with, also, the long train of symptoms invariably to be met with.

He will be directed to cleanse the parts thoroughly, twice a week, with soft soap and water, after which he will apply freely, twice daily, a lotion containing from 30 to 60 grains of hyposulphite of soda to the ounce of water. After the plant is removed the lotion should still be used for a week or two, for, although apparently cured then, it will be liable to relapse. Three or four weeks ought to effect a cure.

Medical Societies.

NORTHERN MEDICAL SOCIETY OF PHILADELPHIA.

Dr. Montgomery read a paper upon Laceration of the Cervix Uteri (for which see page 453.)

Dr. Croasdale asked if there was not difficulty in bringing the surfaces together when operating with the use of the tourniquet.

Dr. Beates asked what were the indications for an operation, stating that he had operated in one case of uterine megrim in which the union was complete, yet with no relief of the megrim. He stated that seventy per cent. of such cases that had been operated upon had failed to relieve this symptom. He would operate if there was menorrhagia even in a slight degree; also, in case of granular degeneration that returned after scraping. He had seen four or five cases out of twenty-five or thirty in which he would not operate. In performing the operation, he placed the stitches as near the surface as possible, including only about one-fifteenth of an inch between the wires, believing that deeper ones were more liable to cut through and loosen. He uses shot and draws them loosely; removes the sutures after nine days; has never had a failure to unite.

Dr. Hall asked if there was any account taken of the menstrual period in selecting the time for operation; also, an explanation of several fissures being found. One rupture, or, at most, two lateral ones, would relieve the strain and allow the head to pass, thus satisfying all the mechanical difficulties and precluding any more.

Dr. Collins said he had not met with an actual case of tearing of the os uteri during labor, and asked for the experience of the other obstetricians present. In performing the operation for relief he had never used the tourniquet.

Dr. Eskridge thought that these cases must be the ones referred to by the older gynecologists under the name of ulcer of the womb. The condition of ulcer he thought very rare, and mentioned that out of two hundred cases examined in one year at the Catharine Street Dispensary, not one of ulcer was found.

Dr. Walker would advise the use of the tourniquet; he had operated without and had been with Dr. Montgomery when it was used. There was a saving of some blood, greater cleanliness, and the surgeon felt in less haste. He thought there was some danger of a thrombus, but there is no record of one having been swept into the general circulation. He had seen Dr. Duer

operate with the patient placed upon the back, which required two assistants, one to support each limb; at the same time it allowed the operator to sit in a comfortable position.

Dr. Montgomery, in reply to the several gentlemen, said that he could see no danger of thrombus, as the tourniquet was not tight enough for that. The supine could have no advantage over the ordinary position of Sims, since he could be seated with the patient in either position. Regarding the time for operating, he made the interval as long as possible before the return of the menses—could usually obtain three weeks. He thought the os might be ruptured in several places at a single labor, but that multiple fissures were usually the result of several labors. He thought it important to emphasize the point of delaying the operation until all tenderness of the womb had disappeared, as one or two lives had been lost from neglect of this precaution. The ease of the diagnosis he thought to depend upon the kind of speculum used; that of Sims being the best. He had met with no difficulty in approximating the parts while using the tourniquet.

Dr. Collins exhibited some specimens of foreign bodies removed. 1st, a bit of wood, $2\frac{1}{4}$ inches long, $\frac{1}{4}$ inch in diameter, taken from the index finger of a boy who had his hand mashed. The stick was partly broken opposite the joint of the finger, so as to allow its motion. The patient was unaware of its presence. 2d, a cigarette holder $2\frac{1}{2}$ inches long, $\frac{5}{8}$ of an inch in diameter, removed from the urethra of a young man who had inserted it during a debauch, two days previously. 3d, a feather, 2 inches long, $\frac{3}{4}$ of an inch wide, expelled from the mouth during a fit of coughing. The patient was subject to a spasmodic cough, which was not relieved by the usual remedies. He had during the treatment examined the throat very carefully with the laryngoscope, and on one occasion saw as far down as the bifurcation of the trachea, without discovering anything wrong. 4th, several small calcareous bodies, $\frac{3}{16}$ of an inch in diameter, coughed up. The patient had been subject to cough for several months; was not relieved until after the expulsion of these bodies. He had examined the lungs several times, but never could detect anything wrong in either.

The calcareous bodies were referred to the committee on morbid growths.

Editorial Department.

Periscope.

Puerperal Convulsions.

At a recent meeting of the Dublin Obstetrical Society (Dublin *Journal Medical Science*) Dr. Richard Henry presented four cases of labor complicated by convulsions. After reading histories of the cases, he said: "In these four cases the distinction between true epilepsy and epileptiform convulsions is well marked, the fit in the former not returning except at the distant intervals the patient is accustomed to, and being no hindrance to recovery. In fact, no particular importance was attached to the fits in the first and fourth cases, once their true nature was apparent. Again, in the second and third cases there is marked distinction. In the second, the anasarca was general, invading the face, arms and legs, while in the third case it was confined to the ankles. In the second case the fits commenced before labor was concluded, and in the third when it was practically at an end. The second was infinitely more serious, and the question suggests itself whether the greater amount of uræmia not only brought on the fits before labor ended, but also increased their number and severity after it was concluded. The number of the fits (seventeen), the profound unconsciousness, the obstinacy of the bowels, and the good results following the old-fashioned practice of bleeding, and, above all, the complete recovery of the patient, are features worthy of note. Again, the question arises, does the bleeding, by speedily lessening the amount of uræmia, and by emptying the blood vessels rapidly, permit the resumption of nervous energy or tone of both cerebral and sympathetic nerves, as shown by quickly returning consciousness on the one hand, and on the other, by the satisfactory motions from the bowels, as both systems seemed profoundly paralyzed by the poison? Also, are there not plethoric cases in whom convulsions might be more speedily cut short, and more safely also, by *bleeding* than by any newer method? I remember a case some years ago, where the patient was bled to forty ounces before the fits ceased; no chloroform was used and she made a good recovery. Dr. Kidd, in discussion said: The fourth case is interesting, as showing that epilepsy occurring during labor is not such a very serious affection as uræmic convulsions. That point is very conclusively established by the paper. I have myself resorted to bleeding, but not with the good results recorded by Dr. Henry. Purging is the remedy on which I chiefly rely. It is often very difficult to get the bowels to act, and in several cases in the Coombe Hospital we have not hesitated to give 20 grains of calomel, and even to add to it some croton oil. The best of our recent observers have noted the good effects of large doses of calomel in cases of uræmia from kidney disease.

Dr. More Madden said: "It appears to me impossible to discuss together with any advantage the general treatment of diseases so essentially distinct as the different forms of puerperal convulsions of which Dr. Henry's paper furnishes us with examples. For instance, the hysterical form of the disease is one requiring little or no treatment of any kind, whereas epileptiform puerperal convulsions, whether uræmic

or not, always require the most active prophylactic and remedial treatment. Still more essential is such treatment in the sthenic or apoplectiform variety of puerperal convulsions, which may be either merely a later stage and more profound degree of the last named form, or may assume its distinct apoplectiform character *ab initio*. Of the value of large purgation, counter-irritation, and cold effusion in such cases, there can be no question. As to chloroform, all the benefit I have seen from its use was to allay for the time the convulsions, and thus aid in gaining time to effect delivery, which must always be a primary consideration in the treatment of these cases. As to chloral and the many remedies which I have seen tried, all I can say is, that in any grave case of true puerperal convulsions time is far too precious to be wasted in trying experiments with such doubtful agents when life is hanging in the scale. In such cases, and I now speak of sthenic or apoplectiform convulsions, bleeding is the only reliable remedy, and I have no doubt that to save the life of a plethoric patient we must still bleed as freely as our ancestors did a hundred years ago, or else the patient will die, as such patients did during the interval of time when bleeding was driven as completely out of midwifery as it was out of every other branch of medical practice."

Dr. Purefoy said: "I have seen a good many cases of puerperal convulsions, and the only case of recovery was one in which the woman was freely bled. I saw a case of a primipara in puerperal convulsions which appeared perfectly hopeless; she was saved by free bleeding."

Dr. Atthill said: "I have been in the habit of bleeding occasionally in convulsions, and have never seen it do harm. Sometimes it seemed to do no good, while, on several occasions, I have seen excellent results follow. Chloroform sometimes stops convulsions; it frequently retards them, but it is not curative. Chloroform is only an expedient to procure the cessation of convulsions till the other treatment acts."

The Chairman concluded the discussion by saying: "I think we ought to keep the different forms of convulsions separate in treatment. The treatment of ordinary uræmic puerperal convulsions is, I think, much the same as of convulsions occurring in Bright's disease. That apoplectic convulsions which depend on anything like effusion into the brain ought to be treated according to the ordinary principles for the treatment of apoplexy, is also, I think, obvious. Uræmic convulsions may, by causing increased tension of the blood vessels of the brain, lead to rupture and consequent apoplectic convulsions; and one object of treatment should, therefore, be to quiet the convulsions. Bleeding lessens the tension; but, on the other hand, it renders the blood more watery, and so increases the probability of the convulsions being repeated. It is obvious, therefore, that all forms of puerperal convulsions cannot be classed together as though they depended on the same cause. Morphia is used to prevent a convulsion taking place. As regards curative treatment, we should separate convulsions occurring before, during, and after labor. As long as there is a child in the uterus, our efforts should be principally directed to removing it; and until that is done it would, I think, be premature to bleed the woman."

Rupture of Bladder.

In the *Lancet*, Dr. Padley records the following case: Towards the end of last June I was called to see Mr. J. S., who had a short time previously consulted me for a syphilitic perforating ulcer of the soft palate. He was suffering from most intense pain in the abdomen, a little above the pubes, attended by sharp rigors and vomiting, and other symptoms of severe pyrexia, which recurred intermittingly from time to time. There was no distention in this region, but some induration and redness and subsequent swelling. The pain, though relieved by opiates, fomentations, etc., continued very acute, and the redness and induration spread rapidly over the abdomen toward the left side. The case was one of severe and extensive phlegmonous erysipelas. There were rapid suppuration and sloughing of the parts, into which I made a free incision, and through which a large quantity of ichorous, offensive discharge freely escaped. Notwithstanding this, the disease spread up the side of the abdomen and chest nearly to the axilla, near which and in the intermediate space other incisions were made and drainage-tubes introduced, the wounds being dressed with carbolic acid lotion. The greatest portion of the subcutaneous areolar tissue of the region, however, sloughed, and had to be removed as it became sufficiently detached. The discharge was immense, and the constitutional symptoms, as may be supposed, were of a very grave character. A few days before my return home, after a short absence, while the patient was straining to empty the bladder, a gush of fluid, "about a tumblerful," suddenly spouted out in a free stream from the wound above the pubes. The urine, for such the fluid proved to be, continued for some weeks to be freely discharged through the orifice, and a little continued to escape occasionally, sometimes at long intervals, when there was more than the usual obstruction to its flow through the urethra, as from mucus, etc., until within a few weeks of his leaving this neighborhood. After the sloughs were detached, the extensive chasms left granulated favorably and cicatrized, a sinus evidently remaining in communication with the bladder, and the patient completely and rapidly recovered his health and strength. An attack of acute pneumonia threw him back for a time, but from this he also made a favorable recovery.

In reply to my earlier inquiries, he at first stated that he had had but little difficulty in emptying the bladder, though the stream of urine was rather small and required more effort to void than formerly, yet not more than had been the case for a long time previously, the bladder being fairly emptied and the urine generally clear. On passing an instrument, however, I found a very close stricture extending through the greatest portion of the canal—at first admitting only a filiform, and afterwards a No. 1, bougie—which no doubt caused greater difficulty in micturition than he admitted, owing, as he afterwards confessed, to his dread of instruments, having formerly suffered much from their use. There

was, he affirmed, never sufficient retention to cause him much inconvenience, and I never found the bladder distended. Up to this attack no pain in this region was complained of.

Such being the facts of the case, what was the immediate cause of the rupture and the discharge of urine? There were, of course, two factors in operation: the sloughing of the abdominal wall and the straining efforts in micturition. Did the perforation of the bladder and consequent extravasation of urine into the abdominal areolar tissue take place in the first instance and set up the cellulitis and sloughing, which afterwards led to the free escape of urine, the pelvic cavity having been protected, and further extravasation prevented, by adhesions around the orifice, a fistulous opening being thus formed? Or were the cellulitis and its consequences, arising from other causes, the primary condition? There can, I think, be little doubt that the first view is the correct one. If so, what caused the rupture? Was it the result of (1) distention and straining, the mucous coat of the bladder having, perhaps, become sacculated and thinned, or even having formed a hernia through the muscular coat, due to the daily repeated efforts to empty the viscus through so small a channel, extending over a very long period of time, and, under a final effort, giving way? or (2) a chronic ulcer leading to perforation under similar conditions? The facts that the patient had at no period suffered any inconvenience from distention of the bladder, and that when I was first called to see him there was no evidence whatever of any such distention, preclude, I think, the former idea; besides which there is, as far as I am aware, no recorded instance of the bladder having been ruptured above the pubes by the mere straining efforts of micturition unaccompanied by some kind of violence. In the only two cases quoted in the leading article, where this accident appears to have been caused by violent action of the abdominal muscles, the rent was found in the back part of the bladder, and in distention from stricture of the urethra the membranous portion of that canal usually first gives way. Besides a case of Mr. Harrison's, referred to in the article, an instance has been recently given by Dr. Call (*Lancet*, Dec. 10th), in which rupture from the latter cause must have occurred in the lower and back part of the bladder, the gush of urine having taken place through the anus. What part gave way in Mr. Harrison's case is not mentioned.

The second explanation, namely, that there was perforation through a chronic ulcer, appears the more probable one. If this were the case, the ulcer must, of course, have been in the anterior wall of the bladder, near the apex; its formation having probably arisen from, or been favored by, the patient's constitutional (syphilitic) cachexia, co-existing with prolonged, severe straining. Adhesions having slowly formed under its influence, between the bladder at that part and the abdominal wall, just above the pubes, thus preventing any escape of fluid into the pelvis, a strong effort in micturition must have finally caused the rupture, and the extravasation of urine into the areolar tissue, with the consequences which followed. By the time the sloughs had separated, a wall of lymph having become organized opposite the perforation, further extravasation was prevented. That this view of the occurrence is the right one is strengthened by the light thrown upon it by a case of Mr. Bartleet's, in the General Hospital, Birmingham, an account of which appeared in the *Lancet* (vol. i, 1876), of which the following is a brief epitome: The patient, an engineer, aged fifty-three, "had always enjoyed excellent health, and followed his occupation uninterruptedly." On stooping, suddenly and rapidly, to pick up a bar of iron, he was seized with severe pain at the lower part of the abdomen, followed by inability to pass his urine, which had to be drawn off by a catheter, the point of which, being brought into contact with the upper part of the bladder when the handle was depressed, occasioned very acute pain. He died on the eighth day after his first attack, with obscure symptoms of deep-seated peritonitis, the symptoms generally having "appeared to point to an acute strangulation of the intestines," for which the patient was at first carefully examined, rather than to the state of things discovered after death. The autopsy revealed a large quantity of solid lymph matting the organs of the pelvis together, especially between the ileum and bladder, about an inch from its apex; and at this part of the bladder, on its posterior aspect, an ulcer was discovered, exactly resembling chronic gastric ulcer. "The ulcer obviously dated further back than the present illness, and had apparently gone through all its stages without any symptoms, and while the patient continued to follow his accustomed occupation." The act of stooping was considered to have caused a slight laceration in the adhesions between the ileum and bladder, which allowed a little urine to be discharged into the peritoneal cavity. The absence of any symptoms of diseased bladder was remarkable, both in this case and in the one I have narrated; the movement to raise the iron bar having been obviously the immediate cause of the "slight laceration" in the one case, and the effort in micturition that of the rupture in the other.

Syphilitic Diseases of the Lachrymal Apparatus.

Syphilitic lesions of the lachrymal gland, of the lachrymal caruncles, and of the lachrymal passages—all, except the latter, of uncommon occurrence—are treated of by Dr. Charles S. Bull, Surgeon to the New York Eye and Ear Infirmary, in the New York *Medical Journal and Obstetrical Review* for April, 1882. Dr. Bull gives a concise summary of the meagre literature of the subject, but his remarks are mostly from a clinical point of view. He alludes to a case of affection of the lachrymal gland in his own practice, in which the organ became inflamed in consequence of extension from an orbital periostitis. The entire contents of the orbit having been removed, to relieve the excessive pain, the gland was found generally enlarged, the hypertrophy being mainly due, however, to an increase of the connective tissue elements rather than of the proper glandular structure. Two cases of gummy infiltration of the caruncles, published by Dr. R. W. Taylor, being the first on record, are quoted

in detail, on account of their rarity. Osteo-periostitis gummosa of the lachrymo-nasal canal has not been observed by the author, but Panas, Galezowski, and Larebière are quoted as mentioning its occurrence. Under the head of treatment, the following advice in regard to inflammation of the sac is noteworthy: If the inflammatory action is severe, leading to the secretion of a glairy mucus or muco-pus, with a swelling over the seat of the sac, and there is good reason for suspecting a stricture of the duct, from whatever local cause, in the nose, do not resort to operative interference until internal medication has been tried faithfully. Ophthalmic surgeons are too prone to slit up the canaliculi and incise a stricture of the nasal duct, in cases of syphilitic origin, deeming medical treatment useless in such cases, before even giving it a trial. The use of mercury here must be prompt, and its effect must be rapidly produced, or the disease may extend from the lining of the canal to the bony walls. An excellent method of administering mercury in these cases is to use two drachms of mercurial ointment, by inunction, upon the inner aspect of the arm or side of the chest, and at the same time give the mild chloride internally, in small doses every hour or two, carefully watching for the first symptoms of the action of the drug. In many cases a beneficial effect will be observed on the third or fourth day, and then the mercury may be either entirely discontinued, or given in smaller doses at longer intervals. In many cases complete recovery follows such a course of treatment; all signs of inflammation and obstruction in the duct disappear, and its patency is restored without any incision or probing.

Removal of Benign Tumors of Breast Without Mutilation.

Professor T. Gaillard Thomas, Surgeon to the New York State Woman's Hospital, contributes to the April number of the "New York *Medical Journal and Obstetrical Review*," a paper in which he expresses himself in favor of removing benign tumors of the breast as a rule, because the mere presence of a tumor in the breast usually renders the patient apprehensive, nervous, and often gloomy, while, with our present improved methods of operating, the patient is exposed to slight risks, the danger of growth of the tumor is removed, and with this disappears at the same time that of the subsequent degeneration of a benign into a malignant growth. If in addition to these advantages, we can add the avoidance of all mutilation to the person, we have strong grounds for departing from the practice of non interference. The method of operation described Dr. Thomas has practiced thus far in a dozen cases. He distinctly states that it is entirely inappropriate for tumors of malignant character, and that it is applicable neither to very large nor to very small benign growths, being insufficient for the former and unnecessarily radical in its character for the latter. The growths for the removal of which he has resorted to it have been fibromata, lipomata, cysts, and adenomata, and have varied in size from that of a hen's egg to that of a duck's egg or a little larger. The operation is thus performed: The patient standing erect and the mamma being completely exposed, a semicircular line is drawn, with pen and ink, exactly in the fold which is created by the fall of the organ upon the thorax. This line encircles the lower half of the breast at its junction with the trunk. As soon as it has dried the patient is anæsthetized, and with the bistoury the skin and areolar tissue are cut through, the knife exactly following the ink line until the thoracic muscles are reached. From these the mamma is now dissected away until the line of dissection represents the chord of an arc extending from extremity to extremity of the semicircular incision. The lower half of the mamma which is now dissected off is, after ligation of all bleeding vessels, turned upward by an assistant and laid upon the chest walls just below the clavicle. An incision is then made upon the tumor from underneath, by the bistoury, a pair of short volsella forceps is firmly fixed into it, and, while traction is made with it, its connections are snipped with scissors, the body of the tumor being closely adhered to in this process, and the growth is removed. All hemorrhage is then checked, and the breast is put back into its original position. Its outer or cutaneous surface is entirely uninjured, and the only alteration consists in a cavity at the former situation of the tumor. A glass tube with small holes at its upper extremity and along its sides, about three inches in length and of about the size of a No. 10 urethral sound, is then passed into this cavity, between the lips of the incision, and its lower extremity is fixed to the thoracic walls by India-rubber adhesive plaster, and the line of incision is closed with interrupted suture. In doing this, to avoid cicatrices as much as possible, very small round sewing-needles are employed; these are inserted as near as possible to the edges of the incision, and carry the finest Chinese silk. After enough of them have been employed to bring the lips of the wound into accurate contact, the line of incision is covered with gutta-percha and collodion, and the ordinary antiseptic dressing is applied. If the glass drainage tube acts perfectly, there is no offensive odor to the discharge, and the temperature does not rise above 100°; the tube is in no way interfered with until the ninth day, when the stitches are removed. If, on the other hand, the tube does not appear to perform its function satisfactorily, it is manipulated so as to cause it to drain all parts of the cavity, and warm carbolized water is freely injected through it every eight hours. On the ninth day, when the stitches are removed, the tube is removed likewise.

External Biliary Fistula.

Dr. J. M. Booth thus writes to the *Lancet*:—

The following case, which recently came under my observation, is, by reason of its somewhat rare occurrence, worthy of being recorded:—

The patient, a lady aged seventy-seven, had for ten years suffered from well marked attacks of hepatic colic; and, until three years ago, these occurred at intervals of a few weeks. Toward the end of September, 1878, I attended her

during an unusually severe attack, which lasted for several days. The attack was accompanied by retching and jaundice, but, though the stools were repeatedly searched, no gall-stones were found. Since then she has been entirely free from these seizures, only complaining from time to time of slight pain or uneasiness in the right hypochondrium. In June, 1881, a painful swelling appeared on the right side, which remained some time before it became red and burst, giving exit to a scanty yellowish discharge. Save its persistence, she noticed nothing unusual, until, one night toward the end of December, while preparing to retire, she discovered a hard, black point protruding from the orifice of the wound. As it hurt her on being touched, she had recourse to a hair-pin, with which, after one or two vain attempts, she succeeded in dislodging a hard, black body, about the size of a large pea. Next day two concretions of a similar size were passed.

On calling, I found the objects to be medium-sized gall-stones, about a quarter of an inch in diameter. On examination of the abdomen a depression of the integument was noted round a small wound about a quarter of an inch in breadth, situated on the right side, nearly midway between the umbilicus and the crest of the ilium. A thick, indurated band, of about an inch in breadth, could be felt deeply through the abdominal wall, passing up toward the gall-bladder until it was lost over the site of that organ at the margin of the costal cartilage. A scanty sero-purulent discharge, slightly tinged with bile, continued to ooze from the opening. Several more gall-stones have since been extruded, varying in size from that of a millet-seed to that of a pea. Further than this there is nothing worthy of remark, save that the formation of the fistula and the appearance of the calculi explain the abrupt leave-taking (now three years since) of the patient's periodic and painful visitant.

Reviews and Book Notices.

BOOK NOTICES.

A Treatise on the Science and Practice of Medicine; or the Pathology and Therapeutics of Internal Diseases. By Alonzo B. Palmer, M.D., LL.D., Professor of Pathology and Practice of Medicine in the University of Michigan, etc., etc. pp. 903. New York: G. P. Putnam's Sons, 1882. Price in cloth $5.00; in leather $6.00.

This volume has been prepared with the view of filling a void in medical literature which the author believes to exist, namely, a work on Practice of Medicine and Therapeutics viewed from an American standpoint. It has been stated that climatic causes so influence disease and remedies, that they will assume different phases and present varying degrees of potency in different countries. Believing this to be so, Dr. Palmer has described them as he finds them after a long experience in our own country; which feature alone will make his book a valuable addition to every physician's library.

Lectures on Venereal Diseases. By W. F. Glenn, M.D., Professor of Anatomy and Venereal Diseases in the Medical Department of the University of Tennessee, etc., etc. pp. 259. Nashville, Tenn.: Wheeler & Osborn, Printers, 20 N. Cherry St. 1881.

This a very good book and well worth reading. It consists of a series of lectures delivered on venereal diseases by the author. He assures his hearers of the truth of the comforting doctrine of the curability of syphilis, and makes some very sensible and practical remarks on the period that should elapse between the contraction of the disease and marriage. Syphili-phobia (the dread of syphilis) is a far worse disease to contend with than syphilis, for we can cure the latter, but the former is hard to remove from the mind. We would wish for more space to more fully notice this really good book. The presswork, also, is excellent, type large and clear, though the paper is not so good, but this makes no difference when the material printed on it is so excellent.

Chronic Bronchitis; its Forms and Treatment. By J. Milner Fothergill, M.D. With numerous illustrations. pp. 158. Price $1.50. New York: G. P. Putnam's Sons. 1882.

This book, while intended for practitioners, is designed especially for those about commencing practice. A great consideration in all books is that they may be prepared so as to make pleasant as well as instructive reading. Dr. Fothergill possesses this happy faculty in a marked degree. When he writes he always tells something new, and he does so in easy and attractive language. It must be remembered by authors that all men do not possess an equal power of comprehension. That which may be easily grasped by some minds will prove but unintelligible jargon to others. This author so writes that what he means to convey can be easily comprehended by all, thus making his book a very valuable one.

Physical Education; or, the Health Laws of Nature. By Felix L. Oswald, M.D. pp. 257. New York: D. Appleton & Co. 1882.

Dr. Oswald has written some excellent articles on this subject, and his book is a very good one. He discusses in a sensible and intelligible manner the various laws for the preservation of health, and clearly points out the penalty of their disregard. His language and style are excellent. We are constrained, however, to criticise the tendency he exhibits, more especially in the introductory chapter, to bring religion into a work on hygiene. There is a place for everything, and this is hardly the proper place to discuss religion.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

IMPRESSIONS.

The force or power of impressions is as yet an imperfectly understood factor in physiology or pathology. The old story is familiar to all, of the convicted criminal, who was placed in a bath-tub, and being blindfolded was told that he was to be bled to death. A shower bath was so arranged that the water fell on and trickled from his wrist in the water below. Imagining that he was in reality bleeding to death, though in truth no wound had been made on his body, this unfortunate succumbed, and finally died, merely through an impression, or the force of imagination. It was recently reported that a man who had been vaccinated was subsequently informed that the person from whom the vaccine virus was derived was crazy; he brooded over this fact and finally became crazy himself.

The most remarkable case, however, recently occurred in our city. A woman aged fifty-eight, in apparently good health, suddenly died; her sister, aged fifty-six, was so impressed that she died in a few minutes, and to cap the climax, a third sister, aged fifty-two, who was called on the death of the other two, suddenly died, all within half an hour. Of course, it is most likely that all of these women, who were very fleshy, had some heart trouble, but still, allowing this, it would seem that *impression* must have had much to do with the sudden deaths. It is, to say the least, an interesting field of observation, and one in which much is yet to be learned, and we desire to direct thought in this direction. We would be glad to have our readers furnish us their experience on this subject.

AMERICAN MEDICAL ASSOCIATION.

In a short time this representative body of American Physicians will convene in annual session. It may do no good, but still we will take this occasion to give a little advice. It has been reported that Professor GROSS said of the last annual meeting, in Richmond, that while socially it was a success, professionally it was a failure. We have considered that the form and method of the meetings of the State and American Medical Societies was fundamentally wrong. The system of reading papers we can conceive to be of no good, further than to advertise the readers thereof, while they consume much valuable time. It would seem to us much better for our representative men to annually assemble and openly perform two functions, for which they are supposed to meet:—

1st. Social enjoyment.

2d. To enact rules for the government of the profession.

The papers, to which but few listen, could be given much more publicity in the columns of journals, while, by dispensing with the time consumed in their reading, much more time would be allowed for the transaction of business that would prove of real benefit to the profession, while more time would also be allowed for amusement and recreation, which our hard-worked brethren so much need. This hint may, we trust, be of value to those of our readers who may be delegates to the next meeting of the American Medical Association.

"DIAMOND CUT DIAMOND."

The recent action of the New York State Medical Society concerning homœopaths has been commented upon from various sources, we are glad to say; but the most *severe* thrust has been inflicted by the homœopaths themselves. At a recent meeting of the Homœopathic Medical Society of Lancaster county, the following resolution was unanimously adopted:—

"*Resolved*, That it is the sense of this meeting, that since the practice of homœopathy has established for itself an honorable position in the estimation of the community, against all the opposing forces that the Old School could bring to bear against it, there is no advantage or prestige to be derived by homœopathic physicians in consulting with *allopaths*, and, therefore, the recent action of the *Allopathic* Medical Society of the State of New York, in resolving in future to consult with them, was entirely gratuitous."

The leaders of this movement in New York have ample reason to feel uncomfortable. In their own school they are almost universally condemned; by homœopaths they are ridiculed; but few, outside of their own clique, approve of their action; the *best* members of the profession uniting in the openly expressed hope that the innovating society shall be debarred from participation in the deliberations of the American Medical Association. The point, however, upon which we wish particularly to dwell, is the fact, the degrading fact, to those who engineered the move, that, far from feeling flattered, the homœopaths really ridicule, and laugh in their sleeve at, the action of the notorious *few* who have sacrificed their consciences to—well, to what?

Notes and Comments.

Ammonia Poisoning.

Dr. A. A. Browne reports the following case in the *Canada Medical and Surgical Journal*:—R. W., aged 54, had been drinking heavily for two weeks, and on Sunday evening, Feb 5th, 1882, he took, by mistake, a draught of strong liquor ammoniæ. In a few minutes, when he had discovered his mistake, he fell insensible on the floor. His brother made him swallow some milk, with considerable difficulty. Previous to the accident, he had taken two plates of strong soup. Free emesis was procured, after which he appeared rather better. The vomited matter smelt strongly of ammonia, and contained some blood. Voice husky, but no dyspnœa. At 10 P.M. he was very weak; pulse 130 and weak. He vomited every fifteen or twenty minutes, and the vomited matter was almost pure blood, partly in clots and partly fluid. Pain in the epigastrium was relieved for a few minutes after vomiting, but soon returned. Features pinched, surface generally cool and covered by a clammy sweat. Urine not suppressed. He constantly hawked and endeavored to clear his throat, but the voice, though husky, was not lost. Respiration not impeded. He remained in this condition until about 7 A.M., when the hemorrhage ceased and the vomiting became less frequent. During the day he remained in much the same condition, constantly hawking and unable to retain fluids, the smallest mouthful of water bringing on vomiting almost immediately. He complained of pain on the right side of the chest. Pulse very weak and rapid. Toward evening he became delirious and remained so all night. The next day his condition remained much the same; some delirium, but less noisy. Had morphia, gr. ss, and liquor atropiæ, ɱ\ij, hypodermically, which gave him a comparatively good night's rest. Next morning (February 8th) he seemed easier and much more comfortable. Pulse still very weak; quite rational; cannot retain anything on his stomach; hawks and spits a great deal, and occasionally, but rarely, vomits. In the evening he was much weaker, but sensible, and spoke intelligently of his case, expressing the conviction that he would not recover, and that the mucous membrane of his œsophagus and stomach were sloughing. His opinion seemed to be justified by the odor of what he hawked up, which was exceedingly offensive. Abdomen very much swollen and tympanitic, but little, if any, tenderness. Bowels move involuntarily. His condition remained much the same until he died, of exhaustion, at 4.30 P.M. on Thursday, February 9th, about 94 hours after taking his fatal dose. He was quite sensible until about a quarter of an hour before death.

Urine of Acute Pneumonia.

At a recent meeting of the Medical Society of the College of Physicians (Dublin *Journal Medical Science*), Dr. Walter Smith made a communication relative to a peculiarity observed in the urine of a patient suffering from acute pneumonia. A young gentleman, aged 22, not previously very robust, caught cold. He was seized with rigors, headache, and vomiting, and the temperature ran up to 105°. He complained of intense pain over

præcordial region. On the fifth day the physical signs were detected, of early consolidation, in the base of the left lung. The other lung became involved, and the young man died without ever rallying. Some of the urine passed on the fifth and sixth days was examined. That of the fifth was very turbid with lithates; that of the sixth was nearly clear. Each specimen examined was bright colored and acid; chlorides markedly deficient.

1. *Serum albumen.*—Tested by the usual methods, a very moderate amount could be precipitated; no distinct flocculi.

2. *Serum globulin.*—Saturation of the urine with sulphate of magnesium threw down an abundant precipitate of globulin.

3. The urine, freed from albumen, yielded *an opaque white precipitate with tannic acid*, and also with phospho-tungstic acid, and it was rendered turbid by alcohol. The tannic precipitate dissolved by heat, and was re-precipitated on cooling. These reactions suggested the presence of peptone; but, since the urine, when freed from mucus (by acetate of lead), and albumen (by precipitation along with basis acetate of iron), yielded no color with Millon's test, and failed to give the xantho-proteic reaction, the presence of any albuminoid seems to be negatived. Moreover, all attempts to get the characteristic biuret reaction for peptone ended in failure. The patient had been treated with sulphate of quinia, but direct testing of the urine for that alkaloid gave a negative result. This case elicited some discussion, but without any conclusion as to the nature of the precipitate.

The Chairman (J. W. Moore, M.D.) remarked that the outcome of the case, from a clinical standpoint, was that it afforded another proof that pneumonia is an essential, continued fever, manifesting itself, in connection with the lungs, only after a lapse of a certain period of invasion. In fact, the lesion of the lungs was analogous to the condition of the intestines in typhoid fever, or to the condition of the skin in the exanthemata or eruptive fevers.

Iodoform for Soft Sores.

In the *British Medical Journal*, Dr. Walter Whitehead says that iodoform appears to be one of the most efficacious drugs in the treatment of the syphilitic non-infecting soft sore, when not unduly inflamed. It has, however, the unfortunate counterbalancing disadvantage of attaching to the patient the liability of unenviable suspicion, the public having become keenly alive to its distinctive and penetrating odor, and having also acquired an appreciative knowledge of the principal purpose for which the drug is most frequently used. He has succeeded, he thinks, in obviating this objectionable feature, without, apparently, sacrificing any of the therapeutic advantages of the drug, by using it in the following manner: He first very carefully cleanses and dries the sores, by means of little pledgets of bibulous paper, and then, by means of a camel's hair pencil, applies freely over the surface of the sores a solution of iodoform in ether. The ether rapidly evaporates, and leaves the iodoform uniformly spread in an impalpable powder over the sores. To insure a free application, the latter part of the process may be repeated and allowed to dry. When perfectly dry, each sore is given a coating of collodion, which is allowed to overlap, about a quarter of an inch, the area of each sore. Before the collodion has had time to dry, a pinch of absorbent cotton wool is placed on each patch, as a protection against the rough contact of clothing. This dressing is allowed to remain undisturbed for twenty-four hours, when the firm film which forms may be gently removed and a fresh coating applied. This treatment is continued day by day until all the sores have quite healed. He has found that a piece of gold beater's skin may be substituted for the collodion after the application of the iodoform. This process will suppress the odor, while a further advantage will be gained in the protection afforded by the collodion against auto-inoculation, and also against the risk of contagion from others coming in contact with the sores.

Anatomy, Physiology, and Pathology of the Blood Corpuscles.

Dr. Alexander Duane, of New York, concludes his article upon this subject, in the April number of the New York *Medical Journal and Obstetrical Review*. The article as a whole embraces a historical and critical review of the part played by the corpuscular elements of the blood under normal and pathological conditions. For the red corpuscles the author proposes the term "erythrocytes." He thinks that Hewson's idea, that these corpuscles are spherical sacs, containing a central globule of uncolored substance, although certainly false in the majority of cases, is not indefensible, the appearance of a central spot being due, perhaps, in some cases, as Arndt conjectures, to a residual granule, a relic of those that, according to the latter's hypothesis, once constituted the whole corpuscle. The criticism

is suggested that the means employed by Hayem to demonstrate his "hæmatoblasts" are just the ones that produce disintegration and decolorization of the red corpuscles, resulting in appearances closely resembling what Hayem describes. Norris' colorless, biconcave, discoid forms seem open, Dr. Duane thinks, to a similar objection. Malassez's modification of Gower's hæmatocytometer, does away with one source of inaccuracy in the use of the instrument, since the depth of cell can always be adjusted to exactly 0·2 mm. The author differs with Obrastzow, Arndt, Norris, Flint, and others, in the conviction that nucleation of the white corpuscles is a normal condition, and not attributable to post-mortem coagulation of granular "nuclear matter"—the chief reason for his dissent being that nucleated corpuscles are observed in the vessels of living animals. The erythrocyte of the adult cannot be said to be capable, as a rule, of amœboid movement or of division, although such may be the case under morbid conditions. The remainder of the paper, which does not readily admit of a synopsis, includes a discussion of the formation and destruction of the corpuscular elements, the part taken by them in physiology, and a consideration of certain pathological conditions, notably anæmia, chlorosis, and leucocythæmia.

Treatment of Diphtheria.

In the *British Medical Journal*, Dr. H. Cripps Lawrence thus writes: The following combination of the glycerols of tannin and carbolic acid has proved itself, during a considerable experience of diphtheria and scarlet fever, a highly efficient application in my hands, viz:—

℞. Glycerini acidi tannici, ℥ vij
Glycerini acidi carbol., ℥ j. M.

In the application of glycerine as an absorbent, it is of practical importance that a small proportion of water should be added to it. In order to secure this, a sufficiency of glycerine should be placed in a saucer, and a throat brush dipped in water should first be stirred into the glycerine before applying it to the throat and fauces. The combination above mentioned has been found practically the most efficient proportion for securing the necessary astringent and antiseptic results, without irritation. An application, twice or at most thrice, in the twenty-four hours, secures the utmost benefit the remedy affords. It is seldom that any additional local remedies are required, but it is wise to precede the application of the glycerols with gargling the fauces and washing out the mouth with a solution of permanganate of potash and water, and to use the sulphurous acid spray, the double advantage that follows being that the fauces are the better prepared to benefit from the glycerine, and that the safety of the practitioner is increased in the event of the patient expectorating any false membrane during the act of swabbing. To further increase the safety of the medical attendant, a glass screen placed between him and the patient will afford protection, without limiting the efficiency of the procedure.

Congenital Fistulæ in the Sacral Region.

At a recent séance of the Soc. de Chirurgie, M. Terillon said that he had observed three cases where such fistulæ existed. The first, a man 35 years of age, had from birth a fistula over the sacrum, just between the upper and inner borders of the gluteal masses. This fistula extended to a depth of three centimeters, and gave issue to a liquid containing fat and epithelial detritus. Around this fistula were several others which had supervened on abscesses; there appeared to be no bone lesions. After ablation with the scalpel histological examination demonstrated that the fistulous passage was formed of epidermic tissue.

In the two other cases reported by M. Terillon, the situation and character of the fistula were identical with the one just considered.

These subcutaneous congenital fistulæ are evidently malformations. But what is their signification? Are they cases of spina-bifida in its most simple form? Or is there a retardation in the junction of the two borders of the vertebral to which the term "posterior umbilici" has been applied? M. Terillon inclines toward the latter hypothesis, as there is absence of bone lesions, and also on account of the little depression sometimes observed in infants at this point.

M. Desprès has observed one such case, and adopts fully the same theory regarding their production.

M. Gueniot has remarked the depression at the point spoken of by M. Terillon, in several children.

Primary Epithelioma of the Tonsil.

Dr. D. Bryson Delavan, of New York, relates a case of primary epithelioma of the tonsil, in the New York *Medical Journal and Obstetrical Review*. Cancer of the pharynx, he remarks, although a somewhat rare affection, is one fraught with such serious results that no opportunity for investigating its nature or devising

means for its relief should be lost. That the tonsil should be a favorite point of departure for malignant disease seems not unnatural, when the anatomical position and structure of that organ are considered. The very qualities, however, which render it liable to attack, afford, on the other hand, the greatest possible measure of hope for a favorable prognosis. For, if a diagnosis could be made before the disease had involved the surrounding tissues, the gland might, in most cases, be extirpated with comparative ease, and by the natural passages, thus avoiding the formidable operation by external incision and the almost certain recurrence of the trouble. The paper concludes with a bibliography of the subject.

Treatment of Scrofulous Ulcers of the Cornea.

This is a form of keratitis which often comes under the care of the general practitioner, and as injudicious treatment may lead to the formation of opaque cicatrices, the following recommendations regarding treatment, made by M. Dehenne in *Le Progrès Médical*, may prove of service:—

1st. Instill daily into the eye four or five drops of the following collyrium:—

℞. Atropiæ sulphat (neutral), gr. j
Aquæ destillat., ʒ iiss. M.

2d. Abstain from every form of metallic collyrium, which often leave indelible marks, veritable metallic leucomata. Do not use any collyrium containing eserine, for affections of the cornea are frequently accompanied by iritis, and there would be danger of formation of posterior synechiæ.

3d. Each evening insert between the eyelids, with a small camel's hair pencil, a portion, about as large as a pea, of the following unguent:—

℞. Hydrarg. oxid. flav., gr. xv
Ung. petrolei, ʒ ss. M.

4th. Apply four times daily over the eye compresses soaked in warm chamomile tea.

5th. Administer a tablespoonful of cod-liver oil every morning.

Laryngeal Electrization.

The *Lancet* says that Rossbach has endeavored to discover whether the nerves and muscles of the human larynx can be excited directly by electrical stimulation applied through the skin, and his experiments enable him, he believes, to give an affirmative assurance. An individual was selected, tolerant of laryngoscopic examination, and a knob-shaped, moist electrode was placed midway between the larynx and the sternum, in front of the anterior edge of the sterno-mastoid, being pressed as deeply in as could be without causing much pain. The other electrode was placed in some indifferent situation on the back of the hand. With this arrangement, whenever an opening or closing shock was sent between the poles, on the side on which the electrode was placed in the neck, a distinct contraction could be observed. The vocal cord moved inward in its whole extent, together with the arytenoid cartilage. The closure contraction was the strongest when the cathode, the opening contraction when the anode, was placed on the neck. Immediately after the stimulation a movement of swallowing occurred, which rendered further observation impossible. If the stimulation was made while a note was being uttered, the effect was to increase the pitch without interrupting the sound. The effect is ascribed to stimulation of the recurrent laryngeal nerve.

Experiments with faradization yielded the following conclusions: The passage of a strong current transversely through the larynx, an electrode being placed on each side of the thyroid cartilage, had no effect on the vocal cords or on the arytenoid cartilages. The free upper edge of the epiglottis was drawn forward and its lower part backward. The aryteno-epiglottidean folds were moved inward, together with the false vocal cords. If one electrode was placed on the side of the larynx and the other on an independent place, the effect was the same, but was confined to one side. A slight movement of the vocal cord was produced by an attempt to faradize the recurrent laryngeal nerve of one side, and the effect was still more marked if an electrode was placed over each recurrent laryngeal, a distinct tremor of the arytenoid cartilages being produced. Hence, Rossbach concludes that, in addition to the reflex effect of a painful cutaneous stimulation and to the effect on the larynx of stimulation of the external muscles, electricity applied outside the larynx can directly stimulate, feebly but unquestionably, the laryngeal nerves.

Special Reports.

NO. V.—OPHTHALMOLOGY (Continued).

BY CHAS. S. TURNBULL, M.D.

Congenital Dislocation of the Crystalline Lens; Diplokoria.

As ophthalmological anomalies, P. D. Keyser (*Archiv. Ophthal.* Vol. x, No. III) reports three cases of congenital dislocation of the crystalline lenses, in one (Medical and Surgical

Reporter, July 10th, 1880) aged 26, the lenses were dislocated differently but not symmetrically, as is usually the case. In the R. E. the lens was dislocated inward, and the L. E. directly upward. In the other two cases, which were also anomalies, the lenses were dislocated directly downward, entirely out of the region of the pupil. These two cases were daughter and mother. A case of *double pupil*, diplokoria, in but one eye of a lady aged 26. There was a broad band, 1½ mm. in width, running across, from margin to margin of the iris, at an angle of 110°. It extended only from the extreme pupillary edges of the iris, and was of the same thickness and color and continuous structure of the iris.

Patient had never suffered from any inflammation of the eye. As a congenital anomaly of the iris, it was rare, as occurring in but one eye. By a small incision through the cornea, in the lower and inner quadrant, K. introduced a delicate pair of iris forceps, grasped the band in its entire breadth and cut it off. Then its lower attachment was divided and the protruding iris was replaced from the corneal incision. Pilocarpine solution was instilled into the eye. No inflammation followed, the pupil became round, and the action of the iris has been good ever since.

J. J. Chisholm (loc. cit.) reports two cases of *sympathetic ophthalmia*, as a sequel to cataract extraction, and of iridectomy in glaucoma. Pain and inflammatory process promptly checked by neurotomy of the lost eye. Dr. C. makes the point, *i. e.*, *in an eye in which nerve cutting was effected, there was a complete effacing of a corneal staphyloma.*

Wm. C. Ayres (loc. cit., p. 273) in examining a glioma retinæ endophytum, mentions his discovery of a peculiarly interesting condition, viz: a *gliomatous infiltration of the lens.* The glioma cells had passed both without and within the canal of Petit, along the whole length of the suspensory ligament, up to the lens capsule. When outside of the ligament they seemed to have impinged upon the capsule and passed around it. When within they seemed to have passed directly to the lens and to have forced themselves up beneath the fibres of the ligament, as they attached themselves to the anterior capsule. Though they had not disturbed the continuity of the capsule at any other place, just under the attachment they had broken through and entered the body of the lens. *They had also entered into the body of the capsule itself, and split it into distinct layers, to a distance of some mm. from the capsular rent.*

In another case Ayres, in examining a phthisical eye (phthisical after a severe inflammation in childhood), found *bone within the lens capsule, i. e.*, "the lens was full size, normal in curvature of capsule, while at the same time the body of the lens was entirely replaced by bone. The space within the capsule was filled with true bony tissue, having a perfect system of canals and typical bone corpuscles, with the exception of a narrow zone of connective tissue, *holding the same relative position as the glioma cells in the case of gliomatous infiltration.* Ossification had taken place in layers parallel to the connective tissue next to the capsule, and where these layers of bone were thin, it appeared as if the original fibres had ossified, but, of course, this is impossible, since the lens, being epithelial tissue, cannot ossify."

Dr. Chas. J. Kipp, of Newark, N. J., reports, in brief (*Archiv. f. Ophthal*, Vol. x, No. 3), the *Transactions of the American Ophthalmological Society for* 1881.

Wm. F. Norris, of Philadelphia, read a paper

On the Administration of Anæsthetics in Bright's Disease of the Kidneys, and on some Cases of Sudden Death after Cataract Operations.

Two deaths. In both cases the patients were etherized; both died comatose, and, in both, careful autopsies revealed no organic lesions, except those belonging to Bright's disease. The first patient was a child five months old, and in good health, upon whom he operated by discission. The child recovered consciousness, but died soon afterward. Intense congestion of kidneys, cloudy swelling, and fatty degeneration of epithelium, most marked in the cortical portion. There was no history of hereditary disease. The second patient was a woman, sixty years old, supposed to be in perfect health. Recovery from anæsthesia was prompt. On the evening of the following day she was somewhat feverish, and the urine diminished in quantity and loaded with urates. From fourth to ninth day she sat up and felt pretty well. After that time unfavorable symptoms manifested themselves. On the sixteenth day she was delirious. On the seventeenth day urine was found to contain a small quantity of albumen, and hyaline, and fatty and granular casts. Patient died on eighteenth day after operation. Autopsy showed all organs to be healthy, except heart, in which there was moderate enlargement of left ventricle; and the kidneys, which were markedly congested, and showed increase of interstitial tissue, fatty degeneration of epithelium, and cast material in the uriniferous tubules.

In the discussion which followed the reading of Dr. N.'s paper, Dr. Mathewson, of Brooklyn, said he "had extracted cataracts, under ether, from patients known to have Bright's disease and who recovered promptly." Dr. Carmalt, of New Haven, related two cases in which death followed cataract extraction performed without anæsthetics. In one case death took place four hours after operation, and seemed to be due to shock, which might possibly have been avoided by the use of an anæsthetic; no autopsy. In the other case the patient had had diabetes, from which she had apparently recovered. Dr. C. assisted in the operation. There was no attempt at repair. Patient failed rapidly and died on fourth day. Dr. Norris remarked that the action of ether, in many cases of fatty heart, was beneficial rather than otherwise. Dr. Noyes, of New York, had used ether and chloroform freely in a large number of cases, but had not had a fatal result in consequence. He had used ether when he knew there was Bright's disease, and also in cardiac complications. He is in the habit of using bromide of potassium, and sometimes hydrate of chloral, before the operation, and thinks that in a certain proportion of cases the occasion for the use of anæsthetics has thereby been considerably diminished. It has been his practice, where anæsthetics are given, to produce simply the primary anæsthesia, make the corneal incision, and then allow the patient to fully recover consciousness, which is utilized in the subsequent steps of the operation."

(Concerning the administration of anæsthetics, especially ether, to patients suffering with any form of chronic kidney disease, there seems to be but one opinion, as expressed by all authorities, *i. e.*, that such procedure is, *as a rule, followed by fatal results*, and the weight of testimony confirms this assertion. Nay, it goes further. It condemns such administration as reprehensible, and if operators insist upon setting aside experience, and by so doing trifle with human life, it will not be long before a well grounded suit for damages will bring some careless, or call it obstinate, administrator up with a round turn. We would deprecate Dr. Mathewson's views, if reported correctly, and so also those of Dr. Noyes, if the latter did not beg the question after saying "he had used ether and chloroform freely in a large number of cases;" "where he knew there was Bright's disease and cardiac complications," by adding, "It has been my practice, where anæsthetics are given, to produce the primary anæsthesia, make the corneal incision, and then allow the patient to fully recover consciousness." This we cannot admit as "using anæsthetics freely," or even operating under anæsthesia. In conclusion, we would warn the inexperienced, and would suggest that it will not be many years before juries will refuse to render such verdicts as exonerate the criminally careless administrators of fatal doses of anæsthetics, but they will call for post-mortem examinations of the kidneys, heart, etc., and in proportion as these are found, or known to have been, diseased will they (administrators, operators, etc.) be held responsible. T.)

Of especial interest in this connection is a paper read by Hasket Derby, M.D., of New York, **On Anæsthesia and Non-anæsthesia in the Extraction of Senile Cataract, with Comparative Statistics of 200 Cases.**

The author avoided anæsthetics as much as possible. Of 200 uncomplicated cases of senile cataract 100 were operated under ether, and 100 without anæsthesia. The average age of the patients operated under ether was 67.7, without, 65.8. Loss of vitreous in fourteen with ether, and nine without. The duration of treatment was 18.3 with ether, 16.5 without. Vision, $\frac{1}{10}$ or more, was obtained in eighty-one with ether, and eighty without. Partial success (vision from $\frac{1}{1}$ to $\frac{1}{60}$) in eight cases with ether, and nine without. There was reasonable prospect of success from a secondary operation in two of the last-named operated under ether, and one without. The total failures were nine with ether, and one without. In the discussion which followed, Dr. D. B. St. John Roosa, of New York, and Dr. H. W. Williams, of Boston, thought that the advantages obtained by the use of ether were considerable.

Dr. Kipp, of Newark, thought that the danger of escape of vitreous is much greater than without anæsthesia. Dr. B. Joy Jeffries, of Boston, saw no objection to the use of ether, but does not hesitate to operate without it.

Dr. Little read a paper entitled a *Contribution to the Study of Glaucoma*, in which he gave the details of four cases, all bi-lateral. The patients were all under 20 years of age. Three of the cases occurred in one family. In all cases the eyes were hypermetropic, and in three of the cases the patients suffered also from hemorrhoids. In one of the cases acute fulminating glaucoma was developed twelve hours after the instillation of atropia, and some days later the fellow eye became glaucomatous. The author thinks the fact that three of his cases occurred in one family is especially instructive, as showing a tendency to heredity, and he infers, from the coëxistence of hemorrhoids in three of these cases, and in some others observed by him, that, since in both

diseases textures supplied with a sphincter muscle are involved, a somewhat similar morbid action may take place in both.

Dr. Geo. C. Harlan related a case of *congenital paralysis of the sixth and seventh nerves of both sides.* Patient aged 18, male; marked epiphora and slight haziness of cornea. R. S. $= \frac{20}{120}$, L. S. $= \frac{20}{100}$. The author thought that the complete paralysis of the two abducens, which are so widely separated in their course after they leave the brain, pointed to a central cause and supported the view that they arise from the same nucleus.

Dr. E. W. Bartlett, of Milwaukee, who formerly saw a great deal of *Conjunctival Inflammation after the use of Atropia*, says that since he had used Merk's preparations the difficulty had entirely disappeared.

Dr. F. Buller, of Montreal, reported a case of

Sudden and Complete Blindness after Large Doses of Quinine,

but as the subject had just been confined, and was threatened with puerperal septicæmia, we consider the case too doubtful to mention in detail, especially as the doses of quinine (20 grains, night and morning, for two days) were comparatively small.

Marked Narrowing of the Field, with Diminished Acuteness of Vision (Glaucoma? Kipp) Following the Use of Duboisia,

presumably due to the use of the drug, was the title of a paper by Dr. J. P. Morrell, of Terre Haute.

Dr. Noyes reported a case of

Pulsating Exophthalmos,

which differed in its history and treatment from any on record. A girl, four years ago, after some severe form of fever, was suddenly taken with a pain in the left side of the head, and about the left eye; the globe began to protrude, and within one week there was marked exophthalmos without inflammatory disturbance. For four years the condition of the eye remained substantially unchanged, except that she had occasional attacks of fugitive inflammation. While passing through Dublin, on her way to America, she had a severe attack of inflammation of the eye. On her arrival in New York she came under his observation. He found swelling of the lids, considerable ecchymosis. There was marked protrusion of the globe, and at the lower and inner angle of the orbit a projection was felt, which at first seemed to be a solid growth. Pulsation, however, was felt, and an operation was proposed. Examination under ether showed the tumor to be a distended blood vessel, which came from the orbit, forward, and returned upon a loop. A bruit was heard over the exophthalmos, but not upon the temple. Pressure upon the carotid completely stopped the pulsation, but had no effect upon the protrusion. From this he concluded that it was a purely vascular anomaly, and not wishing to perform so grave an operation as ligation of the carotid, and not being clear with reference to the diagnosis, he decided to ligate the angular artery, and to dissect down to the enlarged vessel, and tie it off. With great difficulty he succeeded in ligating the angular artery. Then dissecting up the protruding vessel, which was as large as a good-sized lachrymal probe, he traced it down, placing one ligature after another in the vessel, and cutting between them. He demonstrated that it was a vein, which he finally ligated at the spheno-maxillary fissure. He then concluded that it was the anterior orbital vein, coming out of the spheno-maxillary fissure, and going back to empty into the cavernous sinus. The wound healed kindly. At the end of six weeks the exophthalmos had disappeared."

Correspondence.

FOREIGN.

Letter from Europe.

Ed. Med. and Surg. Reporter:—

My promise to write you for the Reporter while in Europe has never been fulfilled, but today I determined to write you my first letter. I came abroad to study abdominal and pelvic surgery, but have really been hard at work on surgery of all regions. In order to get that for which I came such a course was necessary in some places. So I have, therefore, simply studied for six months, in the clinics of Europe, surgical operations and the antiseptic method of each clinic. It has been my pleasure to see a very large number of private operations, and thus I have seen the abdomen opened forty-seven times. Five times I have seen extirpation of the whole uterus. But as I have sent to America my Address in Gynæcology, for the State Society, in which I have spoken especially of abdominal and pelvic surgery abroad, I will not speak of it again in this letter. In about 600 surgical operations, independent of laparotomies, which I have been present at, the method of antisepsis has varied with the operator. But I have not seen an operation done in Europe without *complete* antiseptic precautions; Listerism it all is, but varied to some degree by each operator. To shorten my letter, I will here say that Professor Langenbeck is the only operator whom I have seen open the abdomen without spray, and in this instance his patient rapidly developed a peritonitis. Professors Nussbaum, Volkmann and Esmarch use the spray in other operations, but with the latter

operation air, driven by a pump attached to the hospital engine, takes the place of steam. This is of much advantage, as steam clouds the room and condenses upon the windows, shutting off much light. Moreover, this method by air is the cheapest yet devised. Of the very many antiseptic agents yet devised carbolic acid is found in use everywhere, also salicylic acid; but Billroth, Nussbaum, Volkmann, Langenbeck, Küster and Esmarch all use iodoform, either in spray or in powder. All use the impervious cover for dressing. Iodoform intoxication occasionally occurs, and Prof. Küster lost one patient, from whom I saw him remove a multilocular ovarian cyst, from this effect of the drug. The gauzes from the various agents are variously applied, sometimes as compresses, sometimes as handkerchiefs, a handful at a time on this side, and another handful on that side, and a handful on top, and an antiseptic gauze rolled around it all. The mackintosh over all, more gauze roller over this, and it is completed. Thus it is usual to see it. But by Nussbaum and Küster this is completed by Lister's own method; protective to the wound and the Lister bandage over all, secured by an antiseptic gauze roller. At Kiel the antiseptic bandage is somewhat different from the others. Over the wound is placed, while the spray is in operation, some iodoform cotton, and over this a small bag of naphthaline turf; all is secured by a carbolized gauze roller; over this another bag of turf, much larger, and another roller; if a splint is required it is of glass and padded, and secured by antiseptic roller. If a joint has been resected, over all is applied, for one or two hours, an elastic roller. The limb remains elevated while the elastic roller remains. The turf is the innovation of Dr. Neuber, First Assistant to Prof. Esmarch; he is also the inventor of the decalcified bone drain. That the turf is antiseptic there is but little doubt. Neuber opened the abdomen of five rabbits, and into the peritoneal cavity of each he put a teaspoonful of the turf. This was four months ago. One rabbit died soon afterwards, and tubercle was found in its lungs; possibly a verification of Cohnheim's theory. The remaining four rabbits are living, and look well; they are fat and lively, each with a spoonful of the turf sealed up for months in their bellies. The antiseptic dressing of Neuber is difficult to excel. For instance, by his method, which consists of carbolized spray in the atmosphere during an operation, the addition of iodoform spray in the wound before closing it, the introduction of the decalcified drain, the punching of a few circular holes in the skin, and the turf dressing as I have described it, wounds are rarely ever dressed but once. No pus, no fever, nothing; when the dressing comes off the patient is well. Thus Prof. Esmarch and Dr. Neuber treat all amputations, including the hip joint, all resections of joints. They have shown me cases where the dressing was still intact, the operation having been done four weeks before. The temperature schedule shows remarkable freedom from fever. I saw Prof. Esmarch resect the knee joint to-day, and so dress the leg; this dressing is expected to stay there until the patient is well. The parts once brought together stay there. I have not seen a poultice in Europe, nor half a dozen roller bandages of the old sort. The common drain is of rubber tube. On the extremities all operations are bloodless. In Prof. Esmarch's clinic, to-day, he resected the knee joint, and there *was absolutely not one drop of blood lost; not a single sponge or cotton pledget was used.* He brought the tissues together, applied Dr. Neuber's dressing and an elastic roller and splint. Not a *single artery was tied.* This patient goes to bed with the expectation of not being again hurt by a re-dressing. Prof. Esmarch has used this method in over one hundred cases. Can any one, in the present condition of antiseptic surgery, as seen in Europe, imagine anything so frightful as the common practice of a past surgical era, of draining wounds with strips of bandage, daily washing of them, and all the old practices. They are about gone in Europe, and will go in America, when surgeons are surgeons, and not jacks of all branches of the trade and masters of none.

R. Stansbury Sutton, M.D.

Kiel.

Vaccine Tuberculosis and Vaccine Syphilis.

Ed. Med. and Surg. Reporter:—

The Reporter of March 25th contains the comments on this subject, of Dr. I. Cappie Shand, copied from the *Medical Press and Circular*, from which I make this short extract: "I am of opinion, with reference to vaccination, that it should be optional, although apparently desirable, and that it should be put upon such a footing as to prevent it from propagating such diseases as tuberculosis and syphilis." This is Dr. Shand's opinion. Mine is, that no physician should venture to disseminate such dangerous doctrines without some foundation stronger than the very meagre and insufficient evidence he has offered. The most experienced vaccinators, and those who have had most to do with the treatment of infantile ailments, agree in the belief that disease is not communicable by vaccination. Mr. Marston, an English physician, in the performance of more than fifty thousand vaccinations, "has never seen other diseases communicated with the vaccine disease. Mr. Lees, with equally extensive experience, gives similar testimony. Dr. W. Jenner, who in six years had some thirteen thousand sick adults and children under observation, states "That in no case had he reason to believe, or even to suspect, that any constitutional taint had been conveyed by one person to another, by vaccination." Dr. West "treated twenty-six thousand infants and children" with a like experience. In opposition to all this overwhelming evidence, Dr. Shand describes one or two rather suspicious cases, which prove nothing. For a single case in point, I will relate the history of a case of tubercular disease alleged to have been transmitted by vaccination. A neighboring physician, some years ago, vaccinated a child, who not very long ago thereafter developed scrofula and died. The mother was loud in her denunciation of the doctor for causing her child's death by the use of infected virus. Subsequently she had a second child, whose health she was determined should not be endangered by this same cause, and vaccination was dispensed with. Un-

fortunately for her hopes, however, this child also developed scrofula.

In regard to syphilis being carried in vaccine lymph, I am a non-believer; but, admitting its possibility, there is, practically, very little danger. There are comparatively few cases of infantile syphilis, and no competent physician would think of using virus derived from such a source; if not from conscientious motives, then, in view of the prospect of a prosecution for malpractice. These imputed dangers are mere bugbears; but the matter in dispute might be easily tested without exciting the fears of the public, by confining the experiments to operations on condemned criminals—Guiteau, for instance. In like manner vaccination might be available as a test for insanity, for the learned experts who were examined in the case of that self-inspired assassin, decided that insanity is not only a bodily disease, but that it is also frequently hereditary.

Even if syphilis should prove to be transmissible in the way supposed, it affords no serious objection to compulsory vaccination, for syphilis in its early stage is readily cured, and, therefore, infinitely less to be feared than confluent smallpox. It is a curious fact that all the actual cases of infantile syphilis that come under notice can be traced to sources other than vaccination, and yet so few fears are expressed on the subject.

JOHN T. HUDDLESON, M.D.

Glen Mills, March 30th, 1882.

NEWS AND MISCELLANY.

Official List of Changes of Stations and Duties of Medical Officers of the United States Marine Hospital Service, January 1st, 1882, to March 31st, 1882.

Bailhache, P. H., Surgeon. To proceed to Richmond, Va., as Inspector. January 31st, 1882.

Vansant, John, Surgeon. Detailed as President Board of Survey—physical examination of officers of the Revenue Marine Service. March 18th, 1882.

Wyman, Walter, Surgeon. When relieved by Surgeon Austin, to proceed to Baltimore, Md., and assume charge of the Service at that port. March 4th, 1882.

Fessenden, C. S. D., Surgeon. To proceed to Greenport and Sag Harbor, New York, as Inspector. January 26th, 1882. Detailed as President Board of Survey for the physical examination of pilots. To meet at Boston, Mass., February 16th, 1882. February 7th, 1882.

Purviance, George, Surgeon. To proceed to Gloucester, Mass, to extend relief to shipwrecked seamen. January 12th, 1882. Detailed as Recorder Board of Survey for the physical examination of pilots. To meet at Boston, Mass., February 16th, 1882. February 7th, 1882.

Austin, H. W., Surgeon. To proceed to Cincinnati, Ohio, and assume charge of the Service at that port, relieving Surgeon Wyman. March 4th, 1882.

Godfrey, John, Passed Assistant Surgeon. When relieved by Passed Assistant Surgeon Goldsborough, to proceed to New Orleans, La., and assume charge of the Service at that port. March 4th, 1882.

Goldsborough, C. B., Passed Assistant Surgeon. When relieved by Surgeon Wyman, to proceed to Mobile, Ala., and assume charge of the Service at that port. March 4th, 1882. Granted leave of absence for eight days. March 24th, 1882.

Irwin, Fairfax, Assistant Surgeon. Granted leave of absence for seven days. January 18th, 1882.

O'Connor, F. J., Assistant Surgeon. To report to General Superintendent L. S. S., for duty as member of board to examine keepers and crews of the Life Saving Service. January 4th, 1882. Relieved on account of sickness, and directed to report to Surgeon-in-charge, New York, N. Y., for temporary duty. January 18th, 1882. To proceed to Detroit, Mich., and report for duty to the Surgeon-in-charge. February 9th, 1882.

Banks, C. E., Assistant Surgeon. To proceed to Portland, Oregon, and assume charge of the service at that port. March 1st, 1882.

Devan, S. C., Assistant Surgeon. Detailed as recorder Board of Survey—physical examination of officers of the Revenue Marine Service. March 18th, 1882.

Urquhart, F. M., Assistant Surgeon. To report to General Superintendent L. S. S., for duty as member of board to examine keepers and crews of the Life Saving Service. January 18th, 1882.

Kalloch, P. C., Assistant Surgeon. To proceed to New York, N. Y., for temporary duty. January 24th, 1882.

RESIGNATION.

Hebersmith, Ernest. Resignation as surgeon accepted, to take effect November 26th, 1881. January 17th, 1882.

PROMOTION.

Smith, Henry, Surgeon. Promoted and appointed surgeon from January 20th, 1882. January 20th, 1882.

APPOINTMENT.

Kalloch, Parker C., M.D., of Pennsylvania, having passed successfully the examination required by the regulations, was appointed an Assistant Surgeon, by the Secretary of the Treasury. January 23d, 1882.

Directory for Nurses.

The following communication explains itself:—

HALL OF THE COLLEGE OF PHYSICIANS,
N. E. Cor. 13th and Locust Sts.,
PHILADELPHIA, April 20th, 1882.

The difficulty of obtaining competent nurses at the moment when sickness or accident makes them necessary is only too well known. Even if a list of nurses be kept, it is impossible to know who is engaged and who disengaged, and hence, not unfrequently, twenty-four or forty-eight hours, or even more, are passed in anxious and fruitless search over all parts of the city before one can be obtained. At the same moment many excellent nurses are idle, who, if known, would be instantly em-

ployed. What is needed is some way to bring the two classes together– a Directory which will keep a list of all the competent nurses, both male and female, who wish to register, with an accurate record of their addresses, qualifications, charges, engagements, etc., so that physicians and the public in Philadelphia and the neighborhood may, at a moment's notice, be able to procure desirable nurses for all classes of patients, either by application in person, or by telephone or telegraph. Such a plan has been in successful operation in Boston, Mass., for the past two years, and is precisely what we need in Philadelphia.

Accordingly, the College of Physicians of Philadelphia has determined to establish such a Directory, open not only to its own members but to the entire medical profession of this city and neighborhood, as well as to the public. The office, with telephone connection No. 2103, will be in the Hall of the College of Physicians, N. E. corner 13th and Locust streets, and will be open on and after May 15th, 1882, at all hours, day or night. Any person desiring a nurse may apply to the Secretary for information and assistance in procuring one. A list of wet-nurses also will be kept, and, if desired, their freedom from any evidences of syphilis or other constitutional diseases will be certified to by a physician, after a careful and minute physical examination. Lists of nurses for the insane, for children, rubbers, companions, etc., will also be kept.

A committee of ladies interested in the success of the enterprise will assist the Committee of the college in conducting the Directory.

The charges will be as follows:—

For Registration (paid only once by nurse)..	$2.00
After Jan. 1st, 1883, this charge will be..	3.00
For furnishing addresses of disengaged nurses (paid by patient)—	
between 7 A.M. and 6 P.M.	1 00
between 6 P.M. and 10 P.M.	2 00
between 10 P.M. and 7 A.M.	3.00
For finding and sending nurse, an additional	1.00
For wet nurses (uncertified)	5.00
" " (certified after special medical examination)	10.00

All charges must be paid in person or by letter, cash in advance.

When a nurse is ordered by telegraph, the money must be sent by telegraphic money order, in advance.

The success of such an enterprise will depend chiefly on the hearty support of the medical profession. Your attention is therefore called to this matter, and your coöperation is earnestly requested. This can be given best in the following ways:—

1. By sending to the Secretary a list of the names and addresses of all the nurses you can recommend. *Please do this at once.*

2. By inducing all your nurses to register immediately, and

3. *By procuring hereafter every nurse you need through the Directory.* This last is especially important, as it accustoms both patients and nurses to use the Directory, and teaches them its value. If you wish to get one of your usual nurses through the Directory, it will only be necessary to furnish your patient with a list of those you desire. The Secretary will refer your patient to any of them that may be disengaged.

Dr. W. W. Keen, Dr. Albert H. Smith, Dr. S. Weir Mitchell, } *Committee of the College of Physicians.*

Assisted by Mrs. Theodore Justice, 1824 Wallace street; Mrs. M. Fulton, 26 South 18th street; Miss S. Stevenson, 249 South 13th street; Mrs. S. Weir Mitchell, 1524 Walnut street; Miss Emily Thomas, Secretary, N. E. corner 13th and Locust streets.

Statistics of Consumption.

From the Providence *Journal* we note that the statistics of consumption in Providence, R. I., as given in the last two monthly reports of the City Registrar, shows some very surprising and interesting results. Dividing the population and the decedents from consumption into two classes, American and Foreign, *by parentage*, the statistics show that in one class a remarkable change in the mortality from the disease has been going on during the past twenty-five years. While the proportion has greatly diminished among the population of American parentage, it has remained nearly stationary among those of foreign parentage, as the following table demonstrates:

POPULATION OF AMERICAN PARENTAGE.

1856—One death from consumption in 268.2.
1865—One death from consumption in 310.1.
1875—One death from consumption in 415.0.
1880—One death from consumption in 435.2.

POPULATION OF FOREIGN PARENTAGE.

1856—One death from consumption in 262.6.
1865—One death from consumption in 248.8.
1875—One death from consumption in 284.4.
1880—One death from consumption in 268.0.

TOTAL POPULATION.

1856—One death from consumption in 266.
1865—One death from consumption in 280.
1875—One death from consumption in 336.
1880—One death from consumption in 326.

From this we note that in regard to the total population there has been a considerable decrease in the ratio of mortality. It would be interesting to inquire into the causes of this diminution of consumption among a portion of the population; and the reasons why this diminution is in one portion of the population and not in the other.

Practice of Medicine in New Mexico.

Through the courtesy of Dr. W. N. Sherman, we have been furnished with a report of "an act passed by the last legislature to regulate the practice of medicine in New Mexico," from which we extract the salient points.

A territorial board of medical examiners is hereby established, which shall be composed of seven practicing physicians of respectability, the three systems of medicine to be represented as follows: Regular physicians, four; homœopaths, two, and eclectics one.

This board shall issue certificates to all who furnish satisfactory proofs of having received diplomas or licenses from legally chartered medical institutions in good standing.

All examinations of persons not graduates or

licentiates shall be made directly by the board, and the certificates given by a majority of the board shall authorize the possessor to practice medicine and surgery. All certificates must be recorded. The board can refuse certificates to individuals guilty of unprofessional or dishonorable conduct, and may revoke certificates for like causes. Any person practicing medicine without having complied with these requirements shall be punished by a fine not less than $50 nor more than $500. The Code of Ethics of the American Medical Association shall be the standard and rule of decision concerning the professional conduct of members of the medical profession. This act became law March 2d, 1882.

Medical Society of the State of Pennsylvania.

It was feared that the recent conflagration at Titusville would materially interfere with the annual session of this body, which is to be held at that place, commencing May 10th.

The Committee of Arrangements announce that they have ample lodging room in private houses to supply all who come, and that the hotels that are left will feed four hundred, if necessary, and feed them well.

The committee are ready to assign good rooms to all the members and those who may accompany them.

An American Work Translated into Italian.

Dr. Louis A. Duhring, of Philadelphia, has received the first part of the Italian translation of his "Treatise on Diseases of the Skin," the translator being Dr. A. Scambellurri, of Naples. The work is there published by Giovanni Irvene. We are glad to make this announcement, from a patriotic standpoint, since it tends to show the fact that American authors are commencing to be appreciated in Europe, and in justice to Professor Duhring, whose magnificent work stands deservedly at the head of the literature of dermatology.

Mount St. Mary's College.

The famous old Catholic College of this name, located near Emmettsburg, Md., has been closed, owing to the outbreak of an epidemic of malignant scarlet fever. More than one hundred and twenty boys were sent to their homes. Two deaths occurred among the students, and while only one other boy had the disease, it was deemed wise to close the college. In the seventy-four years the college has existed, this is the first time it has been visited by contagious disease.

Items.

—Dr. Lewis, a Chicago opponent of vaccination, has died of smallpox.

—Triplet sons, fifty-two years old, and a father 116 years old, are the boast of Robert A. Wright, a mill hand, seventy-one years old, living in Santa Rosa county, Fla.

—A learned Chinese physician, who has traveled much and studied in Europe, expresses his surprise that medicine is regarded as a reputable profession. In China, it seems, the better classes regard it as humbug and superstition.

—At a French matrimonial agency office: "Oh yes, sir, we have what you want—an orphan of about twenty years of age." "Very good. Is she pretty?" "Not particularly, but she has a fortune of 500,000 f. And, besides, she is consumptive." "Consumptive! Are you quite sure of that?" "Oh, certainly, sir; we guarantee it."

—On March 9th, Mr. Reid's Vivisection Abolition Bill was read for the first time in the British Parliament, and put down for second reading on March 29th. Mr. A. J. Balfour gave notice that on the order for the second reading he will move the following amendment: "That while due provision should be made for preventing the infliction of unnecessary pain on animals, it is inexpedient so to limit scientific investigation as to hinder discoveries which must result in a great diminution of human suffering."

QUERIES AND REPLIES.

A. E. R., San Francisco.—You are right in your interpretation of our editorial of March 11th. By referring to our issue of February 18th, page 192, column 1, you will notice the revised code of ethics as adopted by the New York State Society.

MARRIAGES.

McCARNY—APPLETON.—On April 13th, 1882, at the Haddonfield Baptist Church, by Rev. R. F. Young, Robert H. McCarny, M.D., of Philadelphia, and Miss Mary L., daughter of Samuel Appleton, Esq., of Haddonfield, N. J.

NEVILLE—BROWN.—Wednesday evening, March 23d, 1882, at Chambers Presbyterian Church, by Rev. J. M. P. Otts, W. H. H. Neville, M.D., and Miss Lida T. Brown, daughter of E. D. Brown, all of Philadelphia.

PALMER—PROUTY.—In Newport, Vt., March 28th by Rev. Henry Fairbanks, Lewis M. Palmer, M.D., of Litchfield, Me., and Nellie B. Prouty, of Newport.

SMITH—POTTER.—At the home of the bride's parents, on Walnut Hills, Cincinnati, O., April 5th, by Rev. S. S. Potter, assisted by Rev. J. G. Monfort, D.D., Samuel L. S. Smith, M.D., of San Angelo, Texas, and Miss Elizabeth Ray Potter.

TURNURE—DIXON.—On Tuesday, April 4th, at Nyack, N. Y., by Rev. P. V. Van Buskirk, Dr. Milton Turnure, of Closter, N. J., and Miss Carrie Dixon, of Nyack.

DEATHS.

ALEXANDER.—On Saturday morning, April 8th, at Princeton, N. J., Archibald Alexander, M.D.

BEADLE.—In Poughkeepsie, N. Y, April 5th, 1882, Edward L. Beadle, M.D., in the 74th year of his age.

JACOBY.—On Thursday, March 30th, 1882, at his residence, 161 Bleecker street, New York, Dr. Moses Jacoby.

MANLY.—On Friday, March 17th, 1882, of whooping cough, Josephine A., daughter of Dr. Thomas H. and Olivia B. Manly, aged nine months.

MASON.—In New York, on Thursday, the 13th inst., at his late residence, Erskine Mason, M.D., aged 45 years.

STILLE.—In New Orleans, La., March 28th, Benjamin Stille, M.D., formerly of Philadelphia.

STUDDIFORD.—On April 15th, 1882, Theodore H. Studdiford, M.D., of Lambertville, N. J., aged forty years.

VAN OSTEN.—In this city, on the 5th instant, Dr. James Van Osten, aged fifty-three years.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

SICK HEADACHE.

BY T. CURTIS SMITH M.D.,
Of Aurora, Ind.

Few affections are met with more frequently. Few are less amenable to treatment by a careless prescriber. Few cases but can be more or less completely relieved, if the remote and immediate causes of attacks are well searched out, and assiduous efforts are made for their removal. One great obstacle in the treatment of this affection, with which we so often meet, is the inefficient efforts our patients make in seconding our advice regarding prophylactic treatment. Every one who has been a close observer of these migrainous patients must have noted that preventive measures, skillfully directed, and diligently carried out, will forestall many a fierce assault of the affection, will break the force of the onset, or even entirely prevent any painful suffering. Continued and watchful prophylactic management will, in time, so far remove the disease as to render the attacks light and far between in very many cases. Such continued efforts will be far more likely to be crowned with success where the element of heredity does not too strongly enter the case, than in those where such constitutional tendency already exists. That migrainous attacks may be acquired by any habit, labor, or exposure that by continued wear and attrition breaks down the stamina of the bodily powers, is too evident a clinical fact to need more than simple mention here. Time and again have patients come under my care who had been soldiers in the late war, and who protested that prior to the toils, marches, contests, exposures and privations incident to active military campaigning, they were free from all forms of headache. We meet often with men worn out with their labors in civil life, who, in consequence of nervous breakdown, become afflicted with frequent attacks of sick headache. In other words, the overworn nervous system expresses its undue strain by a storm of head pain with concomitant nausea, vomiting, malaise, etc. Again, we more frequently see this disease in over-worked, over-nursed, extra fashionable or dyspeptic women, and too often in those troubled with some form of uterine disease or functional menstrual trouble. Indeed, the subjects of migraine, to their sorrow, often find that any and everything that disturbs digestion, produces slight constipation, or disturbance of the function of any leading organ, or that a little unusual exposure, irregularity of securing meals, loss of sleep, any sudden strain, over effort or excitement is sure to find a most painfully unhappy expression in a more or less prolonged and furious assault of sick headache. One who is especially subject to such attacks lives in constant dread of such a storm of wretched nervous expression.

I am well acquainted with and have often prescribed for a typical case of this migrainous affliction. He is aged 40 years, of naturally good physique, of good habits, formerly a great smoker, but has ceased from that years ago; never intemperate, always a hard laborer in his early years, and a hard student after the age of twenty; the latter often concurrent with hard manual labor. He entered military service at

twenty-two, where he attained the rank of major in less than two years, and by continued exposure, over marchings, hard-fought contests, privations, etc., coupled with a mind ever weary and restless in his efforts to reach a higher position as well as to thwart and defeat the enemy, managed to see the close of the war with a broken constitution, bringing home a body weighing about 115 pounds, that had weighed 142, and with it a legacy of chronic diarrhœa, dyspepsia and occasional severe attacks of headache, not especially accompanied with nausea, but with great nervous prostration. Soon some of these troubles, as the diarrhœa and dyspepsia, disappeared, and, in a measure, the cephalic pains; but he never reached his former weight and generally averaged twenty pounds less. Hard study and continuous labor in his line of business was sufficient to bring on, at quite regular intervals, sharp migrainous attacks. But for these he never left off from his work until after enduring them for fifteen years. Then they came with such a furious storm, and so oft repeated, as to tell on his strength severely and send him often to bed to watch out a night, or days and nights, of most wretched agony. By this time two hours of severe, continued mental effort would prove to be a certain provoking cause for an assault of the pain. Also any considerable bodily fatigue, unusual excitement, loss of sleep, the too long deference of a meal, even the absence of his usual coffee or tea at meal-times, the eating of an apple or ever so small a lunch between meals, the slightest unusual heat or chill, cold or damp feet, exposure to slight rain; in short, the very slightest event unusual to him, and which a healthy man would not notice, was the unfailing precursor of a migrainous assault of sharp severity. I have known quite a large number of such unfortunate subjects, among both male and female patients. I have given the above case the more fully because it is really a typical case, and many a one who reads it, if greatly subject to sick headache, will behold their own likeness in it. But a few days since a patient called on me with whom I had never before met. He proved to be the exact counterpart of the case above referred to. Another, a lady, whose symptomatic history in all points was similar to these cases, so far as it was possible for one of her sex to be so. No doubt every one of considerable experience has met with and noted such cases, and could multiply them many times over.

It is not my purpose in this paper to enter into the pathology of this affection, as I may do at some future time, but simply to enter its field of symptomatology and treatment, and especially to call attention to *one symptom* that has never been named in connection with it, as far as I know. This symptom, while not of vast importance, goes to help make up a case, and to show, if need be, more clearly the neurotic reflex character of the whole storm of migrainous pain.

Symptoms.—A person who is subject to often repeated attacks of sick headache is generally able to say, one, two or more days before the storm of suffering bursts upon him in sharp cephalic pain and neurotic nausea, that he is threatened with such an assault. The prodromic symptoms are quite clear and numerous. Not always the same in the same person, and certainly not always the same in different subjects. We may not be able to name every prodromic or other manifestation. Certainly every symptom named will not attach to every case that comes under our notice.

Among the first symptoms of an approaching attack in many cases, will be a feeling of very marked exhilaration, very like that produced by an excessive indulgence in strong coffee or tea. With some, this exaltation affects only the nervous system, without in any marked degree affecting cerebration. This symptom, when present, is always one but more frequently two days in advance of the gathering storm. It is like the mariner's calm, when not a ripple disturbs the placid surface of the wide spreading waters. It is "the calm before the coming storm," always auguring a mighty agitation of the on-coming raging elements.

Accompanying this symptom, or following closely upon its heels, is often a markedly craving appetite that will not be appeased by any ordinary meal. If this is allowed its full run, to satisfy it will always precipitate the attack and add to its fierceness. Especially is this so if supper is the excessive meal. Soon after such an indulgence a feeling of general lassitude, physical and mental, comes over the person. The stomach that but a short time before opened its mouth so wide to take in food, and like the grave would never cry "enough," is now weighed down with its load. It can neither throw it off nor readily digest it. The feeling of excessive fullness becomes more distressing, twinges of pain now begin to course through the temporal and frontal regions, the muscles of the nape are sore to pressure and the weight of the garments fitting there produces a sensation as of great weight, which causes the subject to repeatedly raise and throw back his head or push back his collar, as if to lift

it away. There is also marked tenderness on making pressure on the lower cervical and upper dorsal vertebra, especially the seventh cervical and first dorsal. There is a heavy, dull, occipital pain, reflected forward to the sides or crown of the head. Very often there is from the very first a spot on the very crown of the head, as large or larger than a silver dollar, that feels as though a light weight was sitting there all the time, and when the patient's or physician's hand is placed and held there a little while, it seems to be warmer than the surrounding surface. The thermometer will often indicate that the sensation is not without an increase of heat above that of the surrounding area. Sometimes this spot is the central seat of all the severe suffering; a real clavus sensation. Many of these latter symptoms, and more yet to be named, point clearly to the fact that the cilio-spinal centre is pro foundly involved in the pathology of this affection, and that the terminal twigs of the superior division of the trigeminal nerve are the ones, above all others, that will manifest their painful activity in the fierce explosion about to take place.

Returning again to prodromic symptoms, we desire to note that many, perhaps a majority, of these cases have an entirely different prodromal symptomatic history. The subject may to-day be as well as ever in life. But when he goes to bed he has a marked sensation of hunger. If posted as to its meaning he will carefully ab stain from the slightest indulgence in food. This sensation is very often caused, not by real hunger, but by real indigestion. If the seeming hunger induces the person to eat at that hour, he will most likely pass a restless, dreamy night, and on rising, often long before rising, he will note a headache already set in, and the usual chylopoetic manifestations already giving expression to their morbid state. If he is careful not to eat, but go quietly to bed, get as good a night's sleep as possible, he may miss the threatened attack entirely. But he is more likely to be less fortunate. He will probably rise in the morning feeling as though his stomach was already loaded with very partially digested food; or it may be already sour, and there may be some nausea. If now he is careful to eat very little or really no breakfast, or best of all, drink only a teacupful of hot, well-salted water gruel, and then go about his business, taking care not to overdo nor overeat during that day, he may, and most likely will, miss the attack for that time. But if he should be led to eat a hearty breakfast I can insure him that he will not eat much supper the following evening, and very likely sleep but little during the night. This condition of threatening may last over two or three days, notwithstanding the most rigid care. But so surely as any indulgence looking at all to satisfy appetite is allowed, just so surely will the storm burst forth in all its fury. If the subject of migraine has the nerve and patience to persevere in abstinence from more than very small meals, of very light and very digestible food, until an almost uncontrollable hunger comes on, and with it a feeling that if this hunger is not in some measure appeased the headache will surely and certainly come on; he may then eat a very *moderately* full meal, with the assurance that he will at once be relieved thoroughly. He can then go on with his diet and labors as in ordinary health. But if, even now, when this demanding hunger is upon him, he gives full and unbridled license to his appetite, he will very surely suffer the penalty by a more or less fierce paroxysm of migraine, that will likely be quite long continued. If such a person, feeling the hunger before named, at or about bedtime take the precaution to swallow a pretty full dose of pepsin in some acid solution, and then will carefully guard his appetite the next day, he will quite surely escape his enemy.

Again, another class of these migrainous subjects pass through an entirely different routine of prodromal manifestations. They may have a day of happy exhilaration, but are more apt to have one in which light not ordinarily too bright has all at once become painful to the eyes, or surrounding noises not commonly noticed have suddenly become exceedingly annoying and tormenting. Little occurrences that ordinarily produce no chafing now grate harshly on the feelings. A spiteful reply to a best friend may now be heard when the custom has been that of gentleness or even of affection. Again, there are dull, moody feelings, ill forebodings; friendly acts are misconstrued, slights are conceived where no such thing was dreamed of by the person supposed to render it. Best friends are suspected of having turned a cold shoulder. Business, however prosperous, somehow does not move smoothly. Such persons are sometimes the subjects of visionary phenomena of an interesting and somewhat singular character. Dark spots float in the air. Sometimes many circular stars of rainbow hues float, at seemingly vast distances, before the eyes, always moving so as to keep in the field of vision, and often having a rotary motion among themselves. Others may have pass before their eyes, whether shut or open—more likely when shut—beautiful panoram-

ic views, in which variegated colors and beautiful and fantastic figures may pass in rapid succession. The subjects of migraine always know the meaning of all this morbid visual phenomena, and can have a little time to prepare for the on-coming storm, for when these manifestations have been noted, a very severe and agonizing paroxysm may be almost unfailingly looked for within a few hours. In some cases these optical illusions are not manifested until the severe suffering is fairly on.

The sense of hearing may also be the seat of perversions, but such cases have very rarely come under my notice, and I am not prepared to state their character, from any personal observation.

Besides the divisions of cases above referred to, there is yet another, where the person obnoxious to these attacks may rise in the morning feeling as well as usual. He eats and drinks and feels well. But he has a trip to make to some distant point, by rail, or by buggy or coach. Before night he is roaring with sick headache, with no known cause for it only that he has changed his usual routine of living for the day. I am well acquainted with a lady who when she came under my care could not even go to a near neighbor's on a visit, or to a church near by, without being made the subject of the most tormenting attack of sick headache, lasting sometimes two or three days. In some women the menstrual epoch is always ushered in and accompanied with most fearful head pain.

In many subjects a day of constipation is sure to be followed by an attack. Constipation in many is the sure and sole cause of the whole trouble, and can always be relieved by securing moderate or free catharsis. Biliousness is a common precedent. So also is lithuria, or the inactive condition of the renal organs. That these organs become sluggish and fail in the free performance of their functions primarily, and thus give rise to the migraine, I do not in any wise believe. On the contrary, I am reasonably sure that all the chylopoetic symptoms are the result of disturbed nerve power, or of a neurasthenic condition of the nerve centres, which themselves have been weakened or unfavorably impressed by some indiscretion in the manner of living, or in over taxation of physical or mental powers.

I will now refer to a rather unsavory symptom that I have never seen mentioned by any writer, nor heard referred to in any way by any person. This, like those already given, is also premonitory, and very often constitutes the first and most persistent outpost of alarm, never letting up until the force of the attack is past and amelioration is declared. How shall I describe it so there may be no mistake? I will speak plainly, then I shall not be misunderstood. Every one has now and then felt the more or less pressing necessity of visiting the water closet to evacuate the bowels, and yet, from force of the situation, could not for a while respond to this call of nature. In order to restrain the evacuation for a time he must needs bring his volition to bear strongly upon the sphincter ani, and if hardly pressed, will also call into action the levator ani muscle, and there retain the muscles in tonic contraction until such time as he may relieve himself. Well, the symptom I refer to now produces just the sensation, or quite nearly that which is felt by any one who feels the necessity of going to stool and yet must needs wait a while—cannot go just then. In other words, there is a firm, tonic contraction of the sphincter ani fibres, and also of the levator ani muscle. This morbid manifestation is very often among the very first to give warning of the on-coming storm of sick headache. It is also one of the most persistent of the symptoms, for it lasts from the very first to the very close of the assault. Whenever these muscles let entirely loose from their tonic contraction the attack for that time is quite at an end. When this tonic contraction is fairly set up, there is also noted a rather tense or *on-the-strain* sensation of the general nervous system. Soon after this the full outburst of the storm is established.

When we take into consideration the character of the nerve supply of the sphincters and of the levator ani we may at once understand that the neurotic element in this affection quite clearly predominates over that of the visceral or chylopoetic, and that the symptoms referable to these organs arise secondarily and as an outgrowth of neurotic disturbance. That continuous contraction of the sphincters is their normal state is almost too well known to even mention. If such were not the case all evacuations must needs be involuntary. Hence, what we mean by tonic contraction of the sphincters, internal and external, is their painful or more or less distressing grasp of the lower end of the rectum, which continues throughout the inception, rise and decadence of attacks of sick headache.

The sphincters and levator ani are supplied by branches of the pudic nerve, which in turn comes from the sacral, and this latter from the spinal cord. Hence the spinal cord presides over and controls this outlet of the alimentary canal. These muscles are classed among the

voluntary. Now, if this irritable state is present, as I have tried to point out, so as to produce such unpleasant contraction in the earliest part of attacks of sick headache, and so continues throughout, it seems to me to clearly indicate an irritable condition of the spinal nerve centres that give expression in this symptom, in advance of almost any others commonly noted as prodromal, and far in advance of the grosser manifestations. The only special importance in this symptom is its advanced warning of the coming enemy—sick headache—giving time for preparation to meet or prevent the attack; and also in that it points to the neurotic origin of the affection, and in that the spinal nerve centres are early affected as well, no doubt, as those of the medulla. In one case, often noted, this symptom is frequently present, two or three days in advance of the attack of sick headache. At about the time this symptom is noted, the temperature may be found from .5° to 1.5° above normal. I have not yet made a sufficient number of thermometric tests on this point, however, to feel positively assured of its accuracy in many cases.

It is a common expression with persons who are migrainous subjects to say, in response to inquiry, "I am always costive at the time the headache is coming on," or "I never have the headache when I am not constipated." Now I do not believe that these sufferers are always really constipated at such times more than at others. But through the increased reflex action of the spinal nerves, due to abnormal irritability, these sphincters grasp the outlet of the rectum with unnatural tightness and retain the contents there, in this way, an unusually long time, during which the fecal lumps become dry, hard, and difficult of emission. This gives the appearance of constipation, when, in real fact, if a person thus affected would go to stool at his regular time he would most likely effect an evacuation, and so remove one etiological factor of migraine. The sphincters are voluntary muscles, and can, therefore, be relaxed at will. But during threatened sick headache it requires constant volitional efforts to keep them slack.

True, I have spent considerable time and ink on the prodromic symptoms of an attack of migraine. But this has seemed necessary. It is especially desirable to make these clear, for it is only in the early portion of such attacks that treatment is of greatest benefit to the sufferer.

The morbid manifestations of a fully developed assault are quite well known. With most persons there is well marked gastric disturbance. This may result from acute dyspepsia, acidity, a sense of weight or distention in the stomach, or distressing nausea, vomiting, etc. There is sharp pain in the head, generally in one temple, or it is supra-orbital or occipital. It may occupy the crown. Sometimes the whole head is involved. Often the whole man is sick. There is now a rise in temperature, greatly and painfully exalted sense of hearing, and well marked photophobia. A light brought into the room at once excites great suffering, even though the eyes be closed and the head covered. The character of the pain is not always alike. Sometimes it is of the grinding, boring, agonizing character, often aggravated at every pulsation. Again, it is that of clavus, or it is of the most sharp, lancinating fierceness conceivable. Sometimes there is a heavy dull pain accompanied with great distress from nausea or vomiting. During this stage there is great pallor of skin, or the exact reverse of it, according to whether there is determination of blood to the head or not; and there is every grade between these two extremes. Whenever there is an anæmic cerebrum, there, quite surely, will be found a dilated pupil, feeble pulse, and distressing prostration. In such a case the pain is nearly always of the keen, lancinating character, and generally considerable gastric distress without much nausea. In the red and turgescent-faced subject of migraine, there is far more apt to be excessive nausea, some vomiting, and a terrible thumping headache, with contracted pupil, congested conjunctiva, hot, dry skin, and hard, full pulse.

One almost constant symptom in all forms of these attacks is coldness of feet and of hands. Another one of this stage is a heavy soreness and some tenderness of the trapezius and rhomboid muscles. To these, many minor and some graver uncomfortable symptoms might be named, but we forbear, as we yet have a little mercy on the reader. Some distinct types of this affection have not been named here at all.

Treatment.—How to say much in a few words here is difficult to determine. Preventive measures are by far the most effective in producing permanent good. Is the subject overworked in mind or body? Give him rest, if possible. If rest is not attainable, give him as complete rest as you can. A change of labor, or a change of places, of diet, of surroundings, modes of thought, or of associates, the leaving off of tea, coffee, *tobacco and spirituous drinks*, late hours, moderation in venery, moderation in eating, and a careful choice of the food taken, the regulation of exercise and a proper time for it, the avoid-

ance of undue excitement, and of immoderate laziness while using a full diet; all these and many other points need looking after, and demand careful attention at the hands of the physician, in order that he may direct his patient, and help him to avoid bumping against some of these rocks, greatly to his discomfort. The more nearly the migrainous patient approximates a true physiological plan of living, the more surely will he escape the assaults of his bitter enemy. But if he live in violation of the laws of health, he will have frequent occasion, like Ahab of old, to cry out, "Hast thou found me, oh! mine enemy," but unlike Ahab, will not be able to drive him away so effectually, as that he shall never return during this lifetime. Nay, more, the laws of heredity may bind this same enemy to the temples of the children. During the intervals of attacks, in addition to precautions above referred to, a little steady medication may be made quite effective. Dyspeptic trouble should be carefully removed. Also constipation, and any morbid habit of system, when possible. Then, perhaps, no one remedy will yield as much benefit alone, as a long continued use of nux vomica. A pill of ext. nucis. vom., gr. ss, twice or thrice a day for weeks together. Some will not bear so much. To this may be added, a part of the time, gr. $\frac{1}{20}$ to gr. $\frac{1}{10}$ of arsenious acid. If constipation is prominent, add also to the pill aqueous ext. aloes, gr. ss, and fel. bovinum gr. ij to v. The addition of ext. belladona is often beneficial. When all these are combined, it is better to divide the dose into two pills. Sometimes a minute dose of arsenic alone, three times a day, will do much to effect relief in the frequency of attacks. The steady, careful use of galvanism will often prove highly useful. Sometimes iron is needed. Sometimes a bad habit needs only to be corrected. Sometimes the removal of constipation alone, will do the whole work of giving relief. Each case must be met and treated as found. With saying this much as to general treatment, we shall turn now to that needed during an assault of this misery-making affection.

Here we are met at the very threshold with the clinical fact that no two cases are alike, and seldom do we see two cases that will alike yield to the same plan of treatment. Only a careful analysis of each case in hand will ever enable us to meet with ready success in securing relief during the time of attack.

If possible, the patient should be placed in a dark, quiet room, of moderate temperature, and after bathing the feet for half an hour in *hot* water, in which a handful of mustard has been thrown, he should lay quietly down and sleep, if he can. There is a little knack in using a foot-bath that it may not be needed to name. It will do no harm to do so, however. At first, place the feet in water as hot as the feet will bear, throw in the mustard, and every few minutes add a little *hot* water to the foot-bath. This will keep the temperature up, and soon the feet will comfortably bear water very much hotter than at first, and more benefit will accrue to the bather.

If there is great nausea an emetic of fl. ext. ipecac or zinci sulph. will be very advantageous. A large drink of hot water, a pint, two pints, or even more, taken with or soon after the emetic, will be very beneficial in emptying and washing out the perhaps loaded stomach, or one that may contain bile. If there is acidity give soda carb., ʒj to ʒij, and report in a short time, if needed. A saline aperient may be often best. These measures promptly carried out often yield quick relief. If not, then the system is ready for some form of anodyne, or nervous stimulant, or nervous sedative. It is not always that such measures as above named can be carried out, as the business or situation of the patient will not permit it to be done. But whether these or similar means have been adopted or not, the question of immediate relief is one that demands our attention. The sufferings are often so acute that the patient will brook no long delay for relief. What now shall be done? Well, we must take a moment to survey our patient. Has he a dilated pupil, pale skin, cold hands and feet, feeble pulse, great prostration, pain confined to temples or supra-orbital region. If so, and he has a sour stomach, give at once soda bicarb., ʒij in half a glass of water. That puts one obstacle out of the way promptly. Now to such a patient I have many times given very prompt relief by such a formula as this—

℞.	Ext. aconiti rad., fl.,	gtt. iv
	Ext. belladonnæ, fl.,	gtt. iij–v
	Morphiæ sulph.,	gr. $\frac{1}{10}$
	Spts. æth. nit,	ʒss
	Aquæ vel. syrupi,	q. s. M.

Sig.—Take this quantity every ten to twenty minutes until relief is afforded, or until the characteristic effects of the aconite or belladonna become apparent to a marked degree.

Alleviation most always comes before the physiological effects are made very manifest. The different remedies in this prescription may be varied to suit each case. I have one patron to whom I give this formula, in this wise—

℞. Ext. aconiti rad., fl., gtt. xv
Ext. belladonnæ, fl., gtt. x
Morphiæ, gr. ⅛
Spts. ammon. arom., gtt xx.
Or, in lieu of the latter,
Spts. rectificatis. ℥j
Aquæ vel. syrupi, q. s. M.

Sig.—Take at once.

This is repeated with a full or partial dose of aconite in three or four hours, if needed. But generally a single dose so far settles the matter as that he will go about his business without stopping, often becoming entirely free from suffering, or so sufficiently alleviated as not to especially care for the pain. But if I find this patient with a greatly disordered stomach, inactive kidneys or liver, or costive bowels, this dose will not afford thorough relief. It will dull the keen suffering, but there is no real comfort attained until the organs above referred to are brought to a full performance of their proper functions. This may be done by remedies and means named before. But I want especially to name a cathartic, not much in use, that is often happily adapted to many of these cases, and especially to the last conditions above mentioned. I refer to sulphate of soda:—

℞. Sodæ sulphat., ℥ j
Sacchar. alb., ℥ ij–iv
Acid. sulph. arom., gtt. xx
Aquæ, q. s. ℥ viij. M.

Sig.—Stir well and drink at once, or within a short space of time.

This acts as a pleasant and very prompt cathartic, and for many reasons which I cannot now name, it produces a sensibly good effect at once. Lemon juice may be substituted for the arom. sulph. acid, and it will be better given in hot water. It does better work when received by an empty stomach. If possible, it should not be given soon after a full meal. It must be remembered, however, that the large dose of aconite named in the case above mentioned is not a safe one to give in every case. Many persons would be absolutely poisoned by that quantity, given at a single portion.

In very many cases, suiting the description given above, and treated by the plan named, it will be found that a strong cup of hot coffee and a little quiet rest will settle the whole trouble. Also, that sometimes such a patient may have a very keen appetite, which, if moderately indulged, may bring prompt relief. But if the patient be of intemperate habit in the use of coffee or tea, these agents will only add to his sufferings. If his stomach is already encumbered with food, or the tongue shows a heavy yellow coat, or is thick and indented by the teeth, having a white fur all over its surface, it will be unsafe to advise him to eat, however keen his appetite may be. It will but add to his pain, or prolong the attack.

Again, where the attack has been brought on by overwork, and there is marked exhaustion, a full dose of nux vomica alone may and sometimes does afford wonderfully prompt relief. The same is sometimes effected by a dose of ammonia, or of whisky. But the use of the latter is of questionable propriety, even in the most temperate, as it may lead to its habitual and therefore dangerous employment.

But we have yet another class of cases of this same affection, but presenting symptoms exactly the reverse of those we have had under consideration, if we may, of course, except the pain. They are full blooded, red faced, and perhaps fleshy people. In them the head will be hot, face flushed, even turgid, the pulse hard and full, and every systole of the heart will cause a thumping pain to be felt in the head. These cases need the hot foot-bath, perfect quiet, often an emetic given in an *abundance of hot water*, so as to secure easy emesis and free prespiration. If the stomach will receive it, large doses of bromide of potassium will serve a very good purpose. Ergot with it may add to its power. But I prefer the free use of aconite to the ergot here; and it may be given in quite liberal doses. It will soften the systole of the heart better than ergot, and have anodyne advantages far superior to it. The free use of a saline cathartic in such a case will be beneficial and we generally prefer the one above named.

In these cases of full habit with a tendency to congestion the use of arsenic in the interval will produce a very wholesome effect. This will be found especially so where the subject has passed middle life and atheroma has begun, and if there is a sluggish venous circulation, and puffy condition of the face or eyelids, its use is strongly indicated, and should be continued for a long period. If the bromide of potassium be used in the congestive form of sick headache it should be given in large doses frequently repeated.

It will be noted that I have set forth the two extreme conditions under which sick headache is found to exist. One will not see many cases until he will note every grade between these extremes. To meet each case successfully will require very close discrimination and a clear understanding of the nature of this affection and of its therapy. One reason why migraine is a professional opprobrium, is because of the very little attention given to its pathology and to the

proper interpretation of individual symptoms. We will make a few suggestions that will, we think, help to determine the proper course to be pursued in these cases, and then close.

It will rarely be wise to advise strong coffee in sick headache when the patient is an intemperate user of coffee or tea.

It will rarely do well to advise any form of opiate in the congestive form of headache. If the pupil is contracted or contracts quickly under a moderate light, the use of an opiate will be of questionable propriety.

In the congestive sick headache, large doses of potass. bromid. are clearly indicated. In those cases where the congestion is not well marked, but where the pupil is but little dilated or contracts quickly under moderate light, potass. bromid. is indicated in tolerable large doses, *i.e.*, ʒss repeated every half hour until relief is afforded. Aconite may well be added. In all these forms of headache aconite may be used with distinct advantage with the bromide. Sometimes without it.

It will always be wise to correct acidity of the stomach, to open the bowels if costive, or if not already quite free, to stimulate the liver, kidneys, and skin. A hot mustard foot-bath is of great utility in most all forms of sick headache. A tolerably dark, cool, quiet room will be the best resort for these patients during the assault. All business and worry of every kind should be put aside for the time. The patient should, under any form of sick headache, abstain from any but very light, digestible food in very moderate quantities. The exception to this is only found in the real—not apparent—hungry headache, as it is commonly called.

An emetic, a mild one, may be given with marked benefit where there is great nausea, or where there is a load of undigested food in the stomach. In cases presenting the dilated pupil, pallid face, cold extremities, weak pulse, small and frequently repeated doses of morphiæ sulph., with aconite and belladonna, will be found very useful. If the prostration is very marked, arom. spts. ammonia may be also given. Sometimes a pretty full dose of ext. nucis vom. will act like a charm.

Some of these latter cases will tell you never to give them morphia during sick headache, as it always leads to excessive vomiting and a great aggravation of the distress. But if to such a case—the indications being for it—you give morphiæ sulph. gr. $\frac{1}{20}$, or even $\frac{1}{40}$ every five minutes, in a teaspoonful of water, until the pain subsides, your patient will bear it and be surprised at the thorough and prompt relief afforded. I have often tested this practice thoroughly, to my great satisfaction.

ON THE DETERMINATION OF SEX IN GENERATION.

BY T. M. HARRIS, M.D.

Read before the Ritchie County, West Virginia, Medical Society.

The subject of the determination of sex in generation has long claimed the attention of physiologists, and although there have been several theories advanced in regard to it, yet we are compelled to say that it is a subject of investigation on which we have not, as yet, attained to any certain knowledge. It is well understood that in successful coition the ovum of the female is impregnated by the semen of the male ; and that in this union of the germinal elements is involved the development of a new being after the kind of the procreating pair, either male or female. Now, when we reflect that the continuation of the race demands the two sexes ; and also that the best development of the race demands that they should be found in a nearly equal ratio, we are bound to conclude that the sex of the new being is determined by some law; and that this law, or determining cause, is intended to secure the necessary uniformity of ratio in the sexes. It is not my purpose, in this paper, to advance, dogmatically, any theory ; but starting from the above proposition, to call the attention of the members of this Society to a theory that has been advanced, that has about it as much of the air of probability as any that I have seen, in order to elicit observation that may verify or disprove its correctness. The theory is this: That the sexually determining force is found in the excess of sexual desire in the male or the female parent, in the act of coition.

If the passion or sexual desire of the male is greater than that of the female, the result will be a female offspring ; and, on the other hand, if the sexual desire of the female be stronger at the time of conception than is that of the male, the result will be the procreation of a male. In favor of this theory it has been argued that in case the uniformity of ratio in the sexes should be broken in a very marked degree, so that the excess of either males or females would be very great, the necessity would manifestly be the restoration of this ratio; and so if the excess should be on the part of the female sex, it would naturally result that the passion or sexual desire of the female, in the procreative act, would be

stronger than that of the male; and that by the sexually determining force of this stronger passion a male would be produced, thus tending to the restoration of the equilibrium of the sexes; and *vice versa*.

Having placed before you, as succinctly as possible, this theory, I will now proceed to observe that it can only be verified or disproved by a long course of careful observation; and I beg leave to say that I deem the subject of sufficient importance to justify us in giving to it the careful attention that will enable us to claim its justification or rejection.

Being a breeder of Jersey cattle, my attention has been turned to this subject by the pecuniary interest involved. It is especially the case with this breed of cattle, that the males, as a rule, possess but little value, while the females are very valuable. Under these circumstances we naturally desire the propagation of females, and feel a certain degree of disappointment and dissatisfaction when we find a male where we had hoped to secure a female calf. We naturally wish that we knew how to secure a different result; in other words, that we knew how to determine the sex in breeding.

If the above theory be correct, we have the whole matter in our own hands; for we may keep such a number of males that they may never be overworked; in addition to this, we may keep them in such a condition of flesh and blood, by proper feeding and care, that they shall always be warm, strong, and potent in the sexual act.

We may then make assurance doubly sure, by keeping the female from the male until she shall have passed the meridian of sexual excitement, and her desires for the male shall have begun to abate. When under all these conditions, if the above theory be the correct one, we should always secure a heifer calf. And having succeeded in this a sufficient number of times to give us confindence in the theory, we might still further verify it by changing all the conditions, when we ought to have the opposite result. I trust I have now shown that this theory, which I do not claim as my own, but which I am now engaged in verifying as above, is susceptible of demonstration, if it be the correct one. My observations have not as yet been very extensive; but I must say they justify me in further trials, nay, even in putting it fully to the test. I cannot expect the members of this Society, who, unlike myself, have no pecuniary interest at stake, to be interested as much in this subject as I am; but yet, as a matter of scientific research, it is not devoid of interest, and might well challenge your observation. In regard to the human race, we can well see how the contingencies and vicissitudes of life would naturally tend to the equilibrium of the sexes. The ordination of marriage securing the propagation of the race in families and from pairs, we can well see how the varying conditions of the physiological state, both in the male and the female, under all the vicissitudes of life, should tend to keep the sexes pretty nearly equal in numbers. But there are notable exceptions to this rule.

Occasionally we find a family in which all the children are boys, and again another in which all are girls, and in both cases running through the usual number of children for a family. Now here is a field for the verifying or disproving of our theory. If it be correct, we should find, upon a careful scrutiny of the parents, that the family of boys should have a mother of strong sexual propensities, or what we would call an amorous temperament, while the father should be lymphatic and sluggish. Of course, the state of health of the parents should also be taken into the account. And so, in the family where we find the children all girls, the opposite conditions should obtain with the parents. My observations thus far, in this department, have rather tended to confirm the above theory. Again, we sometimes see a man decidedly past the meridian of life, and whose physical vigor is on the decline, marry a young, or a comparatively young and vigorous woman; and in this case my observations are confirmatory of this theory, the children from such a marriage being almost uniformly boys. The case of illegitimate children might also be observed in its bearing on this subject, as the male, in this case, is usually the aggressor—young, vigorous, and impelled by an overbearing, imperious passion. Of course, to make our observations perfect in this case, we should be able to take into the account the actual physical condition, age, temperament, state of health, etc. of both the parents.

Let me now ask you, gentlemen, at the conclusion of this paper, to give some attention, as you may have opportunity, to the subject of it. Let us have it on the list of subjects for investigation, and, from time to time, let us see what bearing the facts we may be able to observe and collect may have, either toward its confirmation or overthrow.

—It is a significant fact that the greatest age is frequently attained by those who have all their lives had rough and scanty fare, but have lived chiefly in the open air. Thus very aged people are frequent among the Irish peasantry.

Hospital Reports.

UNIVERSITY OF THE CITY OF NEW YORK.

CLINIC OF WILLIAM M. POLK, M. D.,

Professor of Obstetrics and the Diseases of Women and Children.

Ulcer of the Rectum.

The first patient whom I shall show this morning, gentlemen, has rather a complicated history, but at the same time one sufficiently clear to give you a very good picture of one of the most distressing conditions to which human nature may be subjected; and yet, on account of the simplicity of the treatment, and the immense relief from suffering to be derived therefrom, it is one of the most satisfactory conditions we have to deal with in practice.

In reply to my questions she gives the following history: She is thirty-three years of age, married, has had four children; her health was good until after a miscarriage, two years ago last fall, since which time she has not been well. She says she has been troubled with the womb, and with back trouble. She thought there was a good deal of inflammation of the womb, with now and then a little bloody discharge. Her courses occur too often, there sometimes being only a week interval, sometimes two or three weeks, sometimes the normal interval. The back trouble to which she alluded is a pain up through the bowels, which continues all the while, compelling her to lie in bed most of the time, as she cannot sit down. She also has very severe pain at the time of movement of the bowels, and loses a good deal of blood, and a sort of throbbing pain continues about an hour after the passage. Her general health has suffered severely. She considers the pain connected with the back or bowel as the worst, and says it practically wears her out.

Now, gentlemen, I have questioned this patient as to her difficulty somewhat at length, and the above is what I have been enabled to obtain from her. It is important, however, in examining the patient, not to ask too many questions suggesting the answer you expect to receive, and following them to infer what you think is the trouble before you have obtained the full history; but, if possible, get from them the symptom or symptoms which they consider most serious, or which trouble them most, letting them, as far as possible, tell their own story without suggestive questions. Here we find that the trouble is not a single one, but she attaches most importance to the rectal symptom. Having thus obtained the patient's own statement of her case, you will proceed to the physical examination.

Now, on asking her whether she has any difficulty in passing her water, she says she has; that sometimes she cannot make it; sometimes going as long as a day and night without urinating. There is not much pain connected with the act. It, therefore, partakes of the character of retention of the urine.

As a result of all this suffering, for she does suffer a great deal, the woman is broken down. She has become incapable of performing her duties without great fatigue; although naturally a great, strong woman, she has now become a nervous, hysterical, irritable person. There is a certain amount of disorder connected with pretty much all of her bodily functions—the function of the bowels, digestion, etc. You see, therefore, a patient in about as distressing a condition as you will often meet with.

Now the question arises, what is the cause of all this? And before we can answer this question we shall have to make a physical examination. We will place the woman in Sim's position, the best position for examining the rectum, in either male or female, and then try to introduce the finger. You see this effort is strongly opposed by the spasmodic action of the sphincter muscles, which are all the more irritable and resisting on account of the diseased condition present. If we did not proceed with extreme care all our attempts at the introduction of the finger would prove of no avail, since the parts are so sensitive and the patient stoutly and persistently resists us. You observe that as soon as I have introduced my finger into the external sphincter she begins to cry out with pain. I have now reached the neighborhood of the internal sphincter, and upon the posterior aspect of the bowel there is a ragged surface, which is exquisitely sensitive. This, then, is sufficient to account for the trouble which she refers to the bowel.

Now let us inquire into the cause of her irregular menstruation. Passing the finger into the vagina, I find that its posterior wall below and next to the rectum is very sensitive. The uterus appears to be a little enlarged. The irregularity in menstruation seems to have been due to a fungous condition of the lining membrane of the organ, following, probably, upon her miscarriage. It is not impossible that a small portion of the placenta may have been retained.

We find nothing abnormal with the urinary passages, and it is probable her retention of urine has been due to an irritable state of the bladder and urethra, caused by her general hysterical condition, from long continued suffering.

We find, then, two troubles existing in this patient, the first pertaining to the uterus, and the other to the rectum. We will first direct our attention to the latter. The lesion of the rectum may have originated simply in a slight break of the mucous membrane, at which point there afterwards set up an ulcerative process, which led, of course, to hyperæsthesia of all the nerve filaments that may be involved, and you know that there is scarcely any other portion of the body which is so freely supplied with nerves as the tissues immediately in the neighborhood of the sphincter ani. The consequence of this ulceration and hyperæsthesia is, of course, extreme irritability of all the muscles of the parts, so that upon the slightest intimation of a painful process, such as the introduction of the finger into the rectum or a movement of the bowel, these muscles are thrown into a spasmodic state of contraction. This serves to increase the pain, so that you have one condition reproducing the other, until the general system is finally affected and suffers. The case is analogous to one of long continued toothache.

In some cases you will find that the lesion is extremely minute, probably no larger than a fissure such as one often has upon the lip in cold weather. Again, there may be an ulcer as large as your thumb nail. In the course of time the ulcerated surface becomes hypertrophied, its edges raised or the centre depressed; in fact, you may find a variety of pathological appearances connected with these lesions; but there is one complaint that will always exist, namely, hyperæsthesia; a hyperæsthetic condition of the nerves distributed to the base of the ulcer.

Formerly this condition of things—the pain excited by these sensitive nerve filaments—was treated by dividing the muscular fibres, the sphincters, whose contraction kept up the compression and motion in the parts; but latterly it has been treated by stretching the muscles to such an extent as to produce a temporary paralysis. In order to perform this operation the patient must be under the influence of ether, and, indeed, it often happens that one is unable to make a satisfactory examination of the patient's condition until she is put under the influence of an anæsthetic. You saw that the examination which I made on this patient a moment ago was by no means satisfactory in enabling me to determine the exact condition of the entire bowel at its lower part, but having examined her before, on a previous occasion, I know pretty well the exact state of things. The pain inflicted by stretching the sphincter is entirely too great to admit for a moment of our doing the operation without an anæsthetic, although before this agent was widely employed the treatment was sometimes resorted to. The surgeon gradually introduced all his fingers up into the rectum, and then doubled up his fist and suddenly, in that position, jerked it through the sphincter. You can imagine the suffering of the poor creature who might have happened to be the patient.

After oiling my fingers, they are gradually introduced into the rectum, and outward traction force is made in either direction, with the hands, gradually increasing it so as to stretch and not rupture the fibres of the sphincter. If sudden and too great force is used the muscles will be lacerated to a greater or less degree, and there will be incontinence of the fæces, for we seldom find rupture of this muscle tending to repair thoroughly. Unquestionably, even as carefully as I have stretched the parts, certain individual muscle fibres have been ruptured, but they have been ruptured, not in masses, but at different points of the circle, and the damage done to the muscle as a whole is very soon repaired, and after healing it will have regained nearly its normal power. Four or five minutes may be employed in the stretching process, passing the finger around from one side to the other of the muscle, so as to have the distention equal in all directions.

Having stretched the muscle sufficiently, there is no speculum which will enable you to examine the parts better than it can be done with Sims', aided by an ordinary depressor. Upon the posterior wall I find the location of the difficulty, which consists in an ulcerated surface about as big as the nail of my ring finger. It is superficial, involving the mucous structure; in its centre is a small depression. This will require some other treatment in addition to the stretching of the sphincter which has been done, and there is none better than applying to it fuming nitric acid, washing the surface then with the bicarbonate of soda, so to prevent the too deep action of the remedy.

It is not unlikely that a second application of the acid will have to be made before this ulcer will heal. Such would not be the case, probably, if there were present simply a fissure. Ulcers of the rectum are among the most difficult we have to treat, and especially is this the case if there be also some constitutional disturbance, as syphilis, in which case the lesion is possibly due to the deposit of syphilitic material. In addition to the local treatment there should be constitutional or general treatment.

With regard to general treatment, the first point regards the bowels. These patients always require such medicines as produce soft movements. The compound licorice powder of the German pharmacopœia is good, as is also a powder made up of sulphur, the bitartrate of potash or Epsom salts, and sugar of milk. Besides these you can use the ordinary mineral waters. In this manner you will obtain semi-solid evacuations and avoid that congestion and irritation of the sphincter ani which is the great cause of the pain in these patients. In addition to this you must see that the general health is cared for. If there be failure of nutrition, besides proper diet, no remedy will be of more service than cod-liver oil. Arsenic, quinine, strychnine, and iron may be given according as they may be indicated. With regard to her uterine condition, that will be treated on a subsequent occasion.

Cancer of the Cervix Uteri.

This woman is about fifty years of age. She had perfect health until four months ago; her circumstances were passably good; she suffered no bodily aches or pains; there was no derangement of function of any of the organs of the body. She had completed the menopause about three years before, and until four months ago, as said before, her health was as good as that of any woman at her period of life. At that time, however, she was suddenly startled by a feeling of something trickling down from the vagina, and, on examination, found some blood, which continued to flow, during three or four hours, quite profusely. It then ceased, and she gave the matter no more thought, until ten days afterward, when it reappeared under almost the same circumstances, lasting this time twenty four hours. These irregular hemorrhages have continued to return, at times, from then until the present. This being the case, her general health became affected, and she was forced to come here, seeking for relief. When she came into the hospital she had the appearance of a woman who had been losing blood; but she suffered from no pain, and remarked, "Doctor, if you will stop that bleeding I will be as well as any woman here." But the moment I put my finger into the vagina I found that she was very far from being as well as any woman in the house. In other words, I found the cause of her bleeding to be an epithelioma of the cervix. Let it be your rule, gentlemen, when a woman who

has passed the menopause a year or two before, comes to you complaining of loss of blood from the vagina, to suspect cancer of the uterus, and in the great majority of instances you will find your fears verified on examination.

The usual appearances of a cancerous development on this part I have spoken about before. They are very well shown in this patient. But the point arises, what shall we do for her? There have been a number of operations proposed. In the first place, amputation of the cervix. This, of course, is based entirely upon the supposition that only so much of the cervix is involved as can be totally removed by the knife, scissors, or galvano-cautery. If, however, the disease has gone up to the vaginal junction, and invaded the deeper portions of the uterine structure, simple excision of the cervix will accomplish nothing. The only resource would be to remove as much of the diseased tissue in this way as we could, then scoop out as much as possible of what remained, using the actual cautery in order to prevent hemorrhage. This latter operation is the only one which can be adopted in the present case, for the disease has gone quite up to the vaginal junction, invading deeper portions of the uterus and neighboring glands. All we can do, therefore, is to get rid, as far as possible, of this fungous-like growth, which is so sensitive to the touch that even a jar is sufficient to produce a loss of blood. If we can remove this satisfactorily, the loss of blood may be checked so that her general health may improve.

With regard to another operation, total extirpation of the uterus, I merely mention it, as it was suggested in the present case, and would say that it was absolutely forbidden on the discovery of involvement of the lymphatics of the pelvis. Total extirpation of the uterus is to be resorted to only in case all the diseased tissue can be removed.

You will observe that after removing this tissue with the scissors, I am able to check hemorrhage by means of the actual cautery, which is kept constantly ready for use during the operation, as considerable hemorrhage may occur at any moment. Of course, we do not perform this operation with any idea of curing the disease, but simply, as far as possible, to relieve symptoms.

KENTUCKY SCHOOL OF MEDICINE.

CLINIC OF J. M. MATHEWS, M.D.,

Professor of Surgical Pathology and Diseases of the Rectum.

Syphilis.

In going through the wards to-day, I selected three cases of rectal trouble to present at this clinic. They are each of special interest, and represent three different types of rectal affections. I have only questioned them as to the symptoms, preferring to complete the examination before the class. It is best always, in these cases, to allow the patients to tell, in their own way, the symptoms and history, in fact everything that relates to their individual case, hence, I shall proceed to question this man concerning his condition. How old are you? Thirty-two. How long have you complained of rectal trouble? Three years or more. What is your principal trouble? Persistent constipation. Do you take purgatives to relieve that? Yes, sir. What do you take? Compound cathartic pills. How many do you take to cause an action? At present six or eight, about 10 o'clock in the morning. Are these sufficient to cause an evacuation? They produce a small, watery action, about 6 or 8 o'clock in the evening. Do you mean to say you pass no natural fæces? I don't understand your question. I mean do you, with or without these pills, ever have a healthy and natural action? I don't. How long since you had such an action? I would say six or eight months. Before that did you have, as a constant thing, natural evacuations? No sir; only occasionally. If you took no purgative would your bowels move at all? No sir. If you take a larger dose than the six or eight cathartic pills you speak of, does it move your bowels more freely? No sir. How do you know? Because I have tried as many as four drops of Croton oil and ten grains of blue mass at a time. What effect did these have? They produced the same small, watery action. Do you have any pain when your bowels move? No sir. Do you pass any blood or mucus? None at all. What is the condition of your general health? I am partially paralyzed. What do you mean by that? The paralysis is of my legs; it is difficult for me to walk. How far can you walk at a time? Likely six or seven squares, at a moderate gate. Do you ever fall? Yes sir. Can you get up again without assistance? Not easily. Can you get into a street car? Not without assistance. What do you weigh? About 180 pounds. Is this your usual flesh? It is perhaps somewhat above. How is your appetite? Very good. Do you indulge it? I do. Do you sleep well? Yes sir. Your general health, then, outside of the trouble named, is good? My general health is, but I havn't finished telling you about this other trouble. The paralysis, I suppose you mean? well let's hear it. I am unable to hold my water as I should. You mean you pass it too frequently? Yes sir, sometimes with difficulty. Have you ever a desire to urinate, and upon attempting to do so, find that you cannot? Yes sir, that's it; often. Are you capable of an erection? No sir; I haven't been for three years. Have you been a healthy man all your life? In a general way, I have. Have you had syphilis? I had it about four years ago. What symptoms had you then? I had a sore, and after that got well, I had sores upon my body and scalp. Did your hair come out? Yes sir, and my whiskers too. Then it was about a year after this attack that you noticed the paralysis and the constipation? Yes sir. Were you treated for syphilis? I took medicine for six months or more. What did you take? I don't know; it was large bottles of something.

Now, gentlemen, we have an explicit history of the patient's trouble, given by himself. It is a question in my mind whether he should be in the medical or the surgical ward. It would not be proper, however, to send him back without an examination for rectal trouble. He presents some symptoms of stricture of the rectum. It is a singular fact that this man has not passed a fecal evacuation for five or six months. This fact alone demands an examination of the bowel.

In making an examination for rectal trouble

of any kind the patient should be placed upon a hard bed, upon the left side, with the knees drawn up toward the abdomen. It is a good plan to have the bowel thoroughly cleansed by an enema just before the examination. This having been done, I introduce my finger, which, you notice, elicits no pain. The rectum appears to be capacious, even to the extent of five inches; in other words, no stricture is detected by the finger. Shall we now say that this man has no stricture? By no means; while in the majority of instances we find stricture of the rectum located within reach of the finger, it is by no means rare to find it located some distance beyond. I now introduce the rectal bougie, No. 7. This instrument is made of rubber, and it does not require to be warmed, being perfectly pliable. This enters about six inches up the gut, where there seems to be an obstruction before it; but you will remember I have frequently told you that the folds of the gut may obstruct the entrance of an instrument. After a persistent trial here, however, you see it will not enter further. Can this be a stricture? The examination indicates that it is. But you will remember this man has said he has no discharge from the rectum. If a stricture exists it is natural to suppose some ulceration also exists, and hence some discharge. Another reason for eliminating stricture is the seat of obstruction. It usually occurs within two or three inches from the anus. Failing to pass this instrument further, the case must be investigated further. The speculum will be of no service here, for with no instrument of that kind yet devised can we see as far into the bowel as indicated by this obstruction. So the next alternative is to introduce the hand into the rectum, in order to detect, if possible, by digital examination, the true state of affairs in the bowel. To do this the sphincter muscle or muscles must be entirely broken down. An anæsthetic must be administered. * * * *

It has been contended by very many of the authorities that the hand cannot be introduced into the rectum of the male. Contrary to this doctrine, I have introduced my hand into the rectum of three different subjects. One was a case very similar to this, in which persistent constipation had existed for years in a syphilitic subject, and I found a stricture in that case, located at the entrance of the sigmoid flexure, fully eight inches up the gut. I dilated it with my fingers, and the patient made what might be called a good recovery.

This is a strong man, and in order to dilate the sphincter muscles sufficiently great force will be required, and to accomplish it successfully different methods have been suggested. That usually practiced is to insert the two thumbs, and by gradual dilatation toward the ischii, overcome the muscle. I have been more successful by oiling the back of my hand, introducing the ends of my fingers all together, and with all the force at my command push the hand beyond the sphincter. You see I am using much force here now, yet I fear no evil result, and I feel the muscle giving way and the hand is introduced. * * * I now find abundant capacity of the lower portion of the rectum, while above, the folds obstruct the passage of my fingers; but by pushing them gradually aside, I am satisfied that I could push my hand on further. There is much danger, however, in this procedure, even if the bowel be in a normal condition. I have gone sufficiently far to satisfy my mind that no stricture exists.

Now, gentlemen, let us ask ourselves what is the cause of this man's obstinate constipation. Let us recapitulate the important symptoms in his case. He had syphilis, undoubtedly, four years ago; a year after he began to complain of paralysis of the lower extremity; he passes his water with difficulty; he has been impotent for two years.

From this recitation of facts, substantiated by the examination just completed, which excludes stricture, I have no hesitancy in saying that his paralysis is due to a syphilitic deposit in the sacral plexus of nerves. From your knowledge of anatomy, you know the distribution of the branches of this plexus to the lower extremities, to the penis, and to the bladder, etc. As an effect of that pressure in the sacral plexus, we have not only the paralysis of the lower extremities, but it extends, in fact, to the bladder and the penis, and we are justified in the conclusion that it extends to the bowels, and in consequence of this arises the inability to pass the fæces.

Dilating the muscle, as we have done here to-day, will have no bad effect, for the reason that it must have been more or less irritable, and after a free dilatation the patient will be able to pass any fecal matter that may accumulate with less difficulty than before.

What shall be the future treatment of the case? He tells us his general health is good outside of the symptoms narrated. Satisfied that his symptoms are directly traceable to the syphilitic cause, he will be placed upon an anti-syphilitic treatment. The object in doing this is to cause an absorption of the deposit in the sacral plexus of nerves. You would at once say, then, that iodide of potassium should be given this man, and you would undoubtedly be correct in the assertion. Therefore we will direct that he have thirty grains administered three times a day. He remarked to me in the ward that his bowels felt as if they were dead. This was an apt expression.

To aid in producing the regular evacuation we must get up some peristaltic action of the bowel. The liver in a subject like this is usually torpid, therefore, to meet two indications we will give the patient a pill composed of $\frac{1}{8}$ gr. calomel, 2 grs. of extract of aloes, and one-fourth of a grain of podophyllin, to be taken three times a day. We shall watch the effect of this pill, and if it is favorable we shall then give him strychnia, looking to his paralyzed condition. It is a question whether electricity would be of any service to this patient. He will come before the class next week.

Coccyodynia.

Case 2.—This woman presents herself for examination, and therefore we will allow her to recite her symptoms, as we did in the other case. How old are you? Twenty three. Married? A widow. Have any children? One. How old is it? Three years. How is your general health? Tolerably good. What do you complain of? Pain in my back. Where? At the lower end.

Is that all you complain of? Yes sir. Have you any piles, or anything of that kind? I think not. Do you have any pain when your bowels move? No sir. Do your bowels move every day? Not every day. Do they ever come out? No sir. Do you ever lose any blood from the bowel? No sir. Have you any discharge whatever from the bowel? No sir.

Well, gentlemen, it would appear from this woman's recitation of her trouble that we are to be cheated out of any rectal case for to-day, and if it were not for the reason that I have seen so very many complain of symptoms which do not seem to indicate rectal affection, and upon examination found that the same did exist, I would not subject this woman to an examination. But under the circumstances I feel justified in examining the case before you. No abnormal appearance is present around the anus externally, and when I introduce my finger she complains of no pain. I press upon the bowel in front, laterally, and you notice she flinches, and says I hurt her. Yet I feel no ulceration, and she has not said that she discharged blood or mucus at any time. Pressing my finger against the coccyx you notice that she complains of great pain. Catching the bone between my finger and thumb and raising it, elicits more pain. This would seem to indicate that the trouble is located in or around the coccyx. How long, madam, have you suffered from this pain? I had a mild attack of it after the birth of my child, three years ago, which lasted a week or two and passed off; this last attack came on about four or five weeks ago. Is the pain constant? No sir. When is it greatest? When I attempt to get up from a sitting position or move about. These symptoms, together with the facts elicited by an examination, lead to the conclusion that this is a case of coccyodynia. This may be due to many causes; among these we may mention hemorrhoids, fissure of the anus, and other rectal troubles. Of course, under these circumstances, it is but a reflected pain, and when they are relieved the pain of the coccyx ceases. Women who have borne children are most likely to suffer from coccyodynia. It may be caused also by fracture, or dislocation, or disease of the bone. It may be a rheumatic affection of the tendons, or of the muscles, or it may be a neuralgia of the nerves supplying the part. Sometimes the affection is only slight in degree, sometimes very painful. It lasts for an indefinite period. The treatment of this disease must necessarily vary. If you are satisfied, from an examination of the symptoms, that it is rheumatic, the remedies usually given for rheumatism are appropriate—quinine and salicylic acid, etc. If it is due to neuralgia, the remedies for neuralgia are appropriate. The application of a belladonna plaster or a blister over the region would be, in many cases, appropriate.

If all these means fail, and the pain continue, you would be justified in performing an operation for the relief of the patient. Of these there are two, one devised by Dr. Nott, the other by Prof. Simpson, either of which may be practiced, according to the inclination of the operator, with good results. Simpson's plan is to insert a tenotomy knife at the lowest point of the bone, passing it between the bone and the cellular tissue to the point of junction with the sacrum, and then withdraw it, making a subcutaneous division of the muscles on the side of the bone. This is to be repeated on the opposite side.

The other operation is to sever the muscles by an external incision, carefully cutting them with a pair of scissors. This is the simpler and better operation. If caries of the bone exist, its removal is advised. This should, however, be practiced as a dernier resort, only.

Factors of Albuminuria.

The *Medical Times and Gazette*, April 1st, 1882, comments on Professor Senator's paper on albuminuria from which we extract the following: He concludes that there may be at least three factors in the production of that condition as it shows itself in disease. These are (1) Changes in the circulation within the kidneys; (2) Changes in the membranes intervening between the blood and the urine; and, (3) Changes in the blood itself. The urine is comparable to a stream fed from two sources, which differ in the amount of water they contain, and in their composition generally, and which do not entirely follow the same laws. The one source—the transudation from the glomerular vessels—is more watery, and yields some albumen, as well as the ordinary constituents of all transudations; the other source—the secretion of the glandular epithelium in the tubules—is, perhaps, less in quantity, free from albumen, but laden with the specific substances of the secretion. A second complicity is that, with increase of blood pressure, the amount of the urine of filtration increases; but it is more difficult to detect albumen in urine thus diluted.

Thirdly, the distribution of the vessels within the kidney is peculiar, and the effect of changed blood pressure on the two sources of the secretion cannot but be unequal. Fourthly, the walls of the vessels, or other membranes, as well as epithelial cells, may be affected, as regards their nutrition, by the changes of blood pressure, and may so become permeable to albumen. Lastly, the lymph-stream in the kidney is dependent upon the blood pressure, and is not without influence on the composition of the urine. Such being the complex conditions of the problem, it is, perhaps, not surprising that there is little agreement among the various experimenters who have sought to influence the blood pressure, and

have therefrom drawn conclusions as to the pathology of albuminuria. Thus, when the blood-pressure has been raised by electrical excitation of the cervical cord, or by the production of dyspnœa, or by poisoning with strychnine or digitalis, there has been ultimately an increase of albumen. But when the series of events is closely scrutinized, it appears that the albuminuria is due, not to the increase of blood pressure within the kidney, but to a prior and initial diminution of the blood-supply, caused by a narrowing of the small vessels. The author is equally dissatisfied with the evidence when the increase of blood-pressure has been brought about by ligaturing large arteries or by cutting the renal nerves. The method of raising the body temperature of an animal in a calorimeter-box appears to him to be the most uncomplicated means of increasing the general blood pressure. Of this nature were his own experiments, and he invariably found that albuminuria was produced by a sufficiently rapid or a sufficiently prolonged elevation of the body temperature to the extent of 3° to 6° Fahr. The kidneys of those of the animals that were killed were boiled, to coagulate the albumen, and the microscopic sections seemed to confirm the otherwise probable conclusion that the glomeruli were especially the seats of the albuminous exudation.

Professor Senator sums up his criticisms and investigations, as regards the blood pressure, with the remark that the greater number of the experiments heretofore made have been erroneously conceived, and the care spent upon them has been to a great extent in vain. From the few passable experiments, and from the corroborative experiences with the human subject, he concludes that heightened arterial pressure in the kidney is by itself capable of inducing albuminuria, provided that the urine becomes at the same time more scanty than normal, from the abstraction of water by other ways. Congestion of the kidney, caused by ligature, for a few minutes, of the renal vein, produced albuminuria, and the albumen in the boiled kidney was found first in the tubules, and secondarily in the capsules. Congestion (from ischæmia) was also produced by ligaturing, for a corresponding period, the renal artery; it was also produced by ligaturing the ureter. In all the instances where congestion was produced by one means or another, albuminuria followed, but the albumen was not always thrown out to the same amount, or in the same part of the renal structure. The various kinds of renal congestion which can be induced by experiment have their counterpart in clinical experience.

The second factor in the production of albuminuria is the degeneration of the renal epithelium, chiefly of the tubular epithelium, but also of that which covers the glomerular tufts of vessels and lines the inner surface of Bowman's capsule. Those who consider the urine to be a glandular secretion free from albumen, must ascribe to the epithelial cells of the kidney the property of preventing transudation from the blood vessels; and those who, like the author, consider the urine to be a mixture of transudation and true glandular secretion, must also refer to a restraining power of the tubular epithelium, the absence of albumen, at least in the glandular part of the secretion. Consequently, disturbances of nutrition and of function in the tubular epithelium, or complete destruction of the latter, would permit the passage of albumen from the blood and lymph into the urine. There is an analogy for that hypothetical case in acute poisoning by phosphorus and by certain other substances. Fatty degeneration of the renal epithelium is one of the most marked points in the morbid anatomy of phosphorus poisoning, and albuminuria is one of the most constant clinical symptoms. There appear, indeed, to have been some differences of opinion as to the existence of the albuminuria; but Professor Senator shows that the weight of evidence is entirely in favor of that accompaniment of phosphorus poisoning, and he gives four experiments of his own which were quite unambiguous. Clinical experience of phosphorus poisoning agrees with the evidence of experiment. In cases also of pernicious anæmia, fatty degeneration of the renal epithelium and albuminuria go together. The albuminuria of the febrile condition is also associated with renal parenchymatous degeneration; but it is associated with other factors as well, and is, therefore, of doubtful import as regards the causation. Lastly, there is a peculiar kind of degeneration of the renal epithelium—coagulation-necrosis—which is caused by certain poisons, such as chromic acid, petroleum, croton oil, and cantharides, and is associated with albuminuria.

The third great factor of albuminuria is the abnormal condition of the blood. This was the earliest assigned cause of albuminuria; and it was, in fact, the humoral doctrine which most naturally came to the front at the time when albumen in the urine was first detected by Cotugno. But that doctrine can no longer be maintained in its original sense. In Bright's disease, including the amyloid and the congestive forms, the immediate cause of the albuminuria is not a change of the blood, but of the kidney. There are, however, cases of albuminuria in which there are neither tissue changes in the parenchyma of the kidney, nor circulatory disturbances; and in such cases it may be said that changes in the blood are the cause. The blood changes causing albuminuria may be not only in the albuminous substances of the blood, but also in the proportion of its constituent parts.

Syphilitic Inoculations Caused by a Sucking Infant.

In the *Lancet*, *April* 1st, 1882, Dr. Simeon Small reports the following: In January, 1881, a woman, aged 45, presented herself at the Infirmary, on account of a sore on the upper part of the right breast, near the nipple, caused, she said, by suckling a strange child. An enlarged gland was found in the axilla. The core was indurated, and was diagnosed as a hard chancre, which healed under treatment, but was followed by constitutional symptoms. The following August she entered the Infirmary for iritis of the left eye, when the following interesting history was elicited. The daughter of our patient, M. D., and who we will speak of as A. K., aged 26, has been twice married. As the result of the first marriage, there were two children. One child

died at four months, of bronchitis; the other is living and healthy. The husband died of consumption. In September, 1880, she was delivered of a healthy child, to the father of which she was subsequently married. Up to this time she had enjoyed perfect health. When, however, her baby was three weeks old, she went out as wet-nurse, and for one night suckled her own and her employer's baby, after which her baby was sent away, and she confined herself to the strange one. The strange baby she described as being about three months old, emaciated, suffering from diarrhœa, with a "rash" on its body. This was the ninth child and all the others had died. After two weeks, during which she nursed this child at night, and only from the right breast, she left the situation, and returned to her own child, whom she resumed nursing. She soon after noticed a soreness at the upper part of the right breast.

In consequence of the discomfort this gave her when the child was put to the breast, she again sought relief from her mother, who partially suckled the child for her. This child, we are told, suffered before long from a sore place on its upper lip, followed by "thrush," and the eventual death of the child on April 23d, 1881.

We return now to our original patient, M. D. It would appear that she had almost weaned her own infant, when she commenced to suckle her little grandchild, and that she used the left breast exclusively for her own and the right for her daughter's child. We have before traced this patient as applying at the Infirmary with the primary sore on the right mamma, and referred to the subsequent constitutional symptoms. Previously to this time it would appear that she had had excellent health. Has been the mother of ten children, of which number seven are living. Of the three who died, one succumbed at eight months, to measles, another at two years and a half, to smallpox, and the third at ten months, to whooping-cough.

Shortly after she came first under my observation, I desired her to bring her daughter, A. K., who happened then to be in Sheffield, to me. She did so, and the facts respecting her acting as nurse were elicited. I do not recollect finding a distinct scar on the breast, but there could be no doubt of her having been syphilized; she had suffered from "secondaries," and a specific roseolous rash was still on her. I may mention here that while, as I have stated, the baby of the daughter, A. K., died, the baby of the mother, being nearly weaned, and at the time she was suckling her grandchild being nursed at one breast only, is still alive and well.

I will now refer to the facts I have been able to learn respecting the suckling baby and its family, and this I am enabled to do by the kindness and courtesy of the family medical attendant, who has freely communicated with me on the subject; but I should add that he has not long been in professional attendance, and the family history was, in a measure, hidden from him. At first the infant appeared healthy; it was brought up by hand, and except a tendency somewhat to snuffle, seemed to be getting on well until it was nearly three months old. Diarrhœa then set in; it became emaciated, and, it is said, assumed an "old look." As this was the last of nine children, all the others dying in the manner to be hereafter mentioned, the parents were particularly desirous of rearing this one, and with this object it was decided to procure a wet-nurse. It happened that in another family a young woman had, just at this time, been wanted also for the same purpose. The parents, in that instance, made every inquiry as to the character and otherwise of the nurse, and were perfectly satisfied. In consequence of the baby, however, not taking to this woman's breast, she at once left. Mr. X., the father of the infant in question, also satisfied himself as to the girl, and engaged her to suckle his child. The medical man says she was the picture of health, and so, indeed, was the baby. After a few days, from a Thursday to a Tuesday, in consequence of her milk disappearing, she left, and the Sheffield young woman, A. K., came upon the scene, with the baby in the condition previously described. A roseolous rash immediately appeared. The nurse was warned of the risk she incurred, and desired if she remained, as the parents were anxious for her to do, to be particularly careful and cleanly as to the breast. These directions she neglected. There could be little doubt now that the child was suffering from specific disease, and under treatment with mercurials it improved, and is now quite well. All Mrs. X.'s previous children had died. The first is stated to have died from hemorrhage of the umbilicus; the second and third were stillborn at seven months; the fourth, fifth and sixth lived until four or five months, and died, it is said, of some chest affection (?). The seventh died at nine months, the eighth was stillborn at seven months, and the ninth mentioned in this paper. Recently (October, 1881) another child has been born, and is up to the present apparently healthy. Little is known about the subsequent history of wet-nurse No. 1. Our search after her has only elicited that her child died, and she herself has left the neighborhood.

The foregoing cases appear to be of interest, not only from the mode of inoculation, instances of which have previously been recorded, but from the number of the sufferers. It is unfortunate that we have been unable to trace the wet-nurse No. 1, not, as must be evident, that she could have been the originator of the infection in our cases; but it would have been interesting to have ascertained if she too had suffered in like manner to A. K. and M. D. Her infant, we certainly learned, had died, but this may have resulted from inoculation or otherwise. The prime source of the infection appears to be clear. The disease was undoubtedly manifest in Mrs. X.'s baby, when A. K. went to suckle it, and the appearance of a distinct specific rash not later than a week after the wet-nurse No. 1 first suckled the child precludes the possibility of her having inoculated the baby, and consequently, the others referred to in this paper. On the other hand, the condition of Mrs. X.'s baby was more that of congenital syphilis, to which the evidence of the material history of premature births, etc., affords support, and would indicate the suckling baby as the innocent cause of infecting A. K., her child, and its subsequent death, and through this latter of inoculating M. D. It will have been observed that A. K. for one night suckled her own child

and her employer's baby at one breast, and this fact, of course, renders it doubtful whether A. K.'s baby was infected from Mrs. X.'s infant, or from its own mother.

Resection of the Spinal Nerve.

The special correspondent of the *Medical Press and Circular*, writing from Paris, says:—

M. Tillaux occupied the whole meeting of the Académie de Medécine with a communication, which, from its novelty and the interest attached to it, merits to be cited in full. A woman, æt. 35, entered in November, 1879, La Charité, presenting an affection not yet described. When her head was supported and maintained in a certain position she felt nothing abnormal, but immediately that the head was abandoned the patient felt it drawn in an irresistible manner, in a position always the same. The chin turned to the left, and the head, by this rotatory movement, reclined on the right shoulder, as in ordinary wry neck, due to retraction of the sterno-mastoid muscle. However, there was no appreciable muscular contraction. The patient, who seemed utterly powerless to control this kind of spasm, experienced excessively acute pain in the left side of the neck, and at a point corresponding to the first cervical vertebræ. M. Desnos, in whose service the patient was, considered the affection to be functional spasm of the muscles of the neck, and treated it for several months by the continued current, the application of the magnet, metallotherapy, etc., but without the slightest benefit, and the patient left the hospital a greater sufferer than when she entered. All work having become impossible, she applied, in May, 1880, for admission to the Hôpital Beaujon, when she was placed under the care of M. Tillaux. Three weeks afterwards, M. Tillaux thinking that the sternal branch of the sterno-mastoid muscle was the cause of this curious kind of torticollis, decided upon the resection of its tendon. The operation in itself was successful. The wound healed rapidly, but the situation of the patient remained exactly the same, and he requested that something more should be done. It was then M. Tillaux thought of resecting the spinal nerve. This nerve, almost immediately on its exit from the posterior foramen, divides into two branches, one, inner, anastomoses with the pneumogastric, and the other, extern, passing first close to the angle of the jaw and across the parotid gland, reaches the middle of the sterno-mastoid muscle, where it divides into two branches, one of which supplies the muscle above named, while the other descends lower down to reach the trapezius, where it loses itself. These two muscles are animated by this external branch of the spinal nerve, but not exclusively. These two muscles play the principal part in true torticollis, and one might naturally hope to arrest functional spasm by modifying their nerve supply. Already stretching had given good results to Mosetig, in an operation he had practiced on a priest. But M. Tillaux, by an experiment in the dissecting room, found that when the spinal nerve was drawn upon, the movement was communicated to the bulb. This fact made him prefer resection to stretching, as he was afraid of producing a lesion of the bulb. Accordingly, on the 15th of December, an incision was made over the posterior border of the sterno-mastoid, and soon the spinal nerve was brought into view, and seized with a blunt hook and resected for the distance of an inch. Immediate union of the wound, with antiseptic dressing, concluded the operation. As to the results, they are satisfactory. The patient is not completely cured, but she enjoys an evident control over the spasm. M. Tillaux thinks that at the end of a couple of months the affection will have altogether disappeared. The question might be asked if the resection might not in some way affect phonation? Claude Bernard, it was true, had considered the spinal nerve in all its divisions as a nerve of phonation. According to him, the external branch, on contracting the trapezius and the sterno-mastoid, contributed to complete and prolong the movements of the thorax during singing, but his patient has not given any evidence of the voice being modified. M. Guèrin observed that the case of M. Tillaux was remarkable, in that resection and simple section of the ninth nerve was practiced. The latter operation was done by him several times in similar cases, which he considered should be classed under the title "spasmodic torticollis," which Amussat failed to distinguish from true torticollis produced by muscular retraction. For the class of torticollis by retraction, the tendons of the affected muscles should be cut, whereas in spasmodic torticollis, on the contrary, M. Guèrin operated by section upon the centre of the muscles themselves, in order to modify their innervation. M. Tillaux has just shown, that in cutting through the centre of the sterno-mastoid muscles, the spinal nerve was included in the section. M. Tillaux replied that he was well acquainted with cases of spasmodic torticollis, but it did not seem to him that his case could be classified under that head, for where there is spasmodic action the movement is *brusque*, and the muscle feels hard to the touch. In this patient the operation of the rotatory movement was gradual, and the slightest obstacle arrested it, and palpation could not discover any contraction of the muscles. This discussion was concluded by M. Guèrin, who confessed that he was inclined to admit that among the spasmodic wry necks, the case of M. Tillaux formed a new kind; but where there is spasm there is always muscular contraction, and subcutaneous section of the muscle can always be tried, not only without danger, but with advantage.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the April number of the *Alienist and Neurologist*, very ably edited by Dr. Charles H. Hughes, of St. Louis. It contains many interesting articles; among others we note the following: "On Different Aspects of Aphasia," by Dr. Mickle, of London. "Aspects of Alcoholism," by Dr. Wright, of Bellefontaine, Ohio. "The Simulation of Insanity by the Insane," by Dr. J. G. Kiernan, of Chicago. "Laws for the Inebriate," by Dr. T. D. Crothers, and much other valuable matter, original and selected.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

THE ADVANCEMENT OF MEDICINE BY RESEARCH.

On March 28th last, a largely attended meeting was held at the College of Physicians, London, to form an "Association for the Advancement of Medicine by Research." Sir WILLIAM JENNER presided and offered the following resolution:—

"That with the view of bringing the legitimate influence of the medical profession more effectively to bear on the promotion of those exact researches in physiology, pathology, and therapeutics which are essential to sound progress in the healing art, an Association be formed, to be called 'The Association for the Advancement of Medicine by Research.'"

He stated that several meetings of members of the medical profession and others interested in the advancement of medical knowledge had been held, to deliberate on the best means of inaugurating an association for the advancement of medicine by research, and it had been determined to call together a representative meeting of men interested in medicine and the sciences on which it rested and with which it was allied, to express or not their approval of the scheme to be submitted to them. Although there were already a number of societies to which those who had made scientific researches might communicate their results, there was at present none to guide research, and this want he hoped this Association would supply. It was not intended that the Association should limit itself to any one object, but being founded on a very broad basis, should carry on its work in all departments. He hoped it would exert its influence on the study of therapeutics, and investigate the effects of sewer gas and foul air upon the human constitution, and in such studies they would want the combined work of physiologists, pathologists, and chemists. Another subject that lay ready to hand was the influence of light, moisture, subsoil, infection, and injury upon tubercular disease. If such investigations were carried out by the right men in the right spirit he was confident the benefits to humanity would be incalculable. Every advance in physiology was a stepping-stone to an advance in pathology, for the latter is founded on the former; and he trusted the proposed Association would aid and stimulate professed physiologists. For the attainment of these objects there was no desire to infringe or evade the law of the land, or even to ask for a repeal or a modification of any part of it.

But it would be the duty of the Association to watch most carefully the workings of existing laws, and to see how far they attain their object, and how far existing machinery may unnecessarily hinder the work of physiologists. He considered it most important that the Association should be guided by men for whom time had tempered zeal with discretion, and who would be able to restrain the ardor of younger men. Such men would be able and would endeavor both to enlighten the public and lessen their morbid sensibilities. It was deemed desirable that the public should be informed that the future progress of medicine rested upon science. Although medicine has at times made great strides by some fortunate or accidental experiment, yet the real substantial advance depended on true scientific research, and on the habit of mind it fosters. The public also need to be taught the

necessity for experiments on living animals, the advantages obtained by them, the amount of pain inflicted, the number of times the experiments require to be repeated, and if the experiments produced any effect upon the moral nature of the investigator. These were the sensible views suggested by Sir GEORGE JESSEL. The Association will consist of representative members from all the scientific professions. Medicine is a comprehensive *so-called* science, depending, for its advancement, more upon the contributions received from collateral sciences than does any other human study or pursuit. Such associations as this will tend to render unnecessary the use of the term *so-called;* they will result ultimately in making medicine really an exact science, in making it "Truth ascertained." Desultory and single-handed investigation will be no longer the rule, but united and concerted action will enable us to deduce definite laws for the recognition and treatment of disease, to which laws the exceptions will be as few as they now are in the more exact sciences. Let us hope that this excellent precedent will be followed in our own country. Every large city ought to have a similar association, when we might reasonably hope to place our science on a solid basis.

UNIVERSITY OF PENNSYLVANIA.

For some time past the Alumni Society of the University of Pennsylvania has been endeavoring to obtain recognition from the Trustees; they asked to be represented in that body, and to have a voice and an influence in the management of their Alma Mater. At last their request has been heard and granted, and as a consequence the Alumni have taken fresh interest in the welfare of the institution. It has now been resolved that, for every third vacancy occurring, the central committee of the Alumni, representing the graduates of the several departments, shall nominate a certain number of candidates, from among whom the choice shall be made. This action cannot be too highly commended. No one can possibly feel that peculiar love for and interest in the welfare of any institution that belongs in an especial manner to the graduates. Who are better calculated to look zealously after its interests? and, in truth, when we descend to the level of common justice, who are so much entitled to representation in the management of an institution of learning, as those who have through years been associated with it; who have contributed to its material welfare and have received from it the foundation for that very knowledge which has in after life rendered them capable of directing the affairs of others. The Provost, who is himself a distinguished alumnus, is now practically the presiding officer of the Board of Trustees, and it has been well for the University that such an innovation was made. This new change is but another step in the right direction, and while commending it highly, we would also advise all other institutions of learning to do the same, at the earliest practical date.

DISEASE-PRODUCING THEATRES.

The *Medical Press and Circular* calls attention to the dangers of theatres as ordinarily constructed. The want of ventilation is already familiar, and need not be further dilated upon. The point to which attention is to be especially directed is the danger from the sudden draughts of cold air. Every one who has ever been in a crowded theatre can recall how very warm it soon becomes, and how over-heated and feverish he feels. When in this condition, the curtain is raised at the beginning of an act, a strong current of cold air becomes perceptible throughout the house. This sudden change is very liable to produce disease; it will naturally determine the blood from the heated surface to the internal organs, and produce congestion of them. There are many bad points about the construction of our theatres, but none really of greater import than this one. It would seem that it would be almost if not quite impossible to overcome this objection, for the following reason: The air in the auditorium is naturally of a higher temperature than that on the stage, or behind the curtain, because it contains more persons and gas lights, and is warmer; therefore, when the curtain is raised, the cold air will, of course, rush,

or be drawn out to supply the place of the warm, thus creating a draught. To avoid the ill effects of this draught (until architects have devised some means of preventing it) we would recommend the following procedure. Have always at hand some loose wrap, and as the curtain starts up, put it about the body, and keep it there for a few minutes, until the cold air becomes mixed with and as warm as that to which you have been accustomed; then remove it and repeat the process at the commencement of every act. In addition, it would be well for those subject to catarrh, or who have weak lungs, to hold a handkerchief over the nose and mouth for a few minutes, for the same purpose. These precautions should also be observed on leaving any warm building on a cold night, and going out into the chilly street. "Great oaks from little acorns grow," you know; so do fatal diseases from trivial causes spring. These slight causes can often be avoided, or their potency aborted, by equally slight precautions. Therefore, will it be well for physicians to be ever on the alert to give these slight hints of warning, that to so many, unfortunately, seem too insignificant to be worthy of a moment's consideration.

"THE FOLLIES OF FASHION."

Just now the medical profession of England are carrying on an energetic crusade against the health-destroying follies of fashion. The movement is quite universal, and seems to give promise of good accomplishments. Recently Mr. Frederick Treves (*Lancet*) delivered a lecture on this subject, which promises good results, since it was a plain, intelligible, matter-of fact exposition of the results of the deadly style of dress in vogue among fashionable women; and was listened to by many of the so-called leaders of fashion. The speaker, among other good points, said: "There is, however, no tyranny so oppressive as that of the *mode*. A woman might as well be dead as out of the fashion. There is something mysterious in this submission, because it is perfectly well known that the rulers of fashion are not its leaders. If the facts were fully and plainly stated, the fashionable intelligence would not announce that at a particular assembly Lady Little Waist wore gorgeous apparel, of such and such material and made in such and such a style, but that Messieurs or Mesdames Snip and Stitch *exhibited a costume* on the person of Lady L. W." This statement will hold equally good in our own country. It is a dismal fact that women who desire to be fashionable seem to imagine that, to accomplish their purpose, they must resort to the most outrageous vagaries of dress, such as are calculated to seriously injure their physical welfare. The terrible habit of spending an evening in an overheated ball-room with low neck and short sleeve dresses, and then going out into the cold night air with but little extra covering, cannot be too strongly condemned. It is a wonder that in every instance such imprudence is not rapidly followed by pneumonia. A medical journal is the proper place for the discussion of such points, since physicians possess great power and influence to mitigate the evil. The family physician, in nearly all cases, is a trusted friend and confidential adviser, in addition to his professional rôle. His wisdom is considered great, and his words carry much weight. If, then, physicians will earnestly combat the evils of dress, and lose no opportunity to battle against them, much good can be accomplished. For foundation stones in this warfare, let them take the following points: Flannel to be always worn next the skin; clothing to be loose and suspended from the shoulders, so as not to constrict any portion of the body; shoes large and roomy; warm covering to the feet, and very little to the head. With these fundamental principles, intelligent common sense will supply the superstructure of advice in every case. Let us sincerely trust that physicians will recognize and utilize the undoubted powers they possess to reform the dress of our women, and to banish from the world much of the sickness and deformity due to our present abominable system or style of fashionable attire. To do so is a duty that physicians owe to their fellow creatures, and he who neglects to utter this little word of warning is, morally speaking, criminally negligent.

Notes and Comments.

Iodide of Potash in Pneumonia.

In the *Moniteur Thérapeutique* we read that M. Riebe has tested, clinically, this medicament, which M. Schwartz considers capable of arresting the progress of pneumonia. M. Riebe used this medication exclusively in thirty-seven cases of pneumonia; in twelve cases there was double pneumonia, and in three others the disease was complicated with pleurisy.

In some cases he was able to commence treatment during the first twenty-four hours, administering every second hour a tablespoonful of the following solution:—

℞. Potass. iodid., ℥iss
Aquæ, ℥vij. M.

A bladder containing ice was placed over the region of the thorax, corresponding to the affected portion of the lung. Of the thirty-seven patients treated, but one succumbed, and in this case the pneumonia was double. M. Schwartz, in 10 per cent. of his twenty-eight cases, succeeded in arresting the malady after the second day.

The results obtained by M. Riebe, although less brilliant, are satisfactory, and should lead to the further employment of a remedy which is at least innocuous in its action.

The preceding year M. Riebe simply followed the expectant method in twenty-two cases of pneumonia in young, healthy soldiers, and found that, generally, the malady was of longer duration than when treated by iodide of potash.

Ranula.

In the *Medical Times and Gazette*, April 1st, 1882, Dr. C. B. Lockwood offers the following note on a case of ranula. It seems to be generally agreed that in almost every case of ranula the cyst has no connection with the ducts of the salivary glands. This point is supposed to be proved by the fact that in nearly all cases a probe can be passed into the sub-maxillary (Wharton's) duct, and no communication discovered between it and the cyst. This method seems to exclude Wharton's duct in a satisfactory manner. There are other salivary ducts in the immediate proximity to which it cannot be applied. There is no particular reason why the ducts of the sub-lingual glands should not be capable of distention and conversion into ranula. E. W., aged fourteen, presented herself with a very large typical ranula beneath the right side of the tongue. It had only been noticed two months. The sub-maxillary ducts were not probed, but appeared free, and discharged ordinary thin saliva. A large piece was snipped out of the cyst-wall and the contents saved. They consisted of about two drachms of a very tenacious, yellow, transparent fluid, of faintly alkaline reaction. A portion was found to be soluble in distilled water, from which it was precipitated white and opaque, by the addition of acetic acid. Solution of perchloride of iron produced no claret-colored reaction; it may therefore be inferred that no sulpho-cyanide of potassium was present. Added to starch solution, and kept for some time at a gentle heat, no conversion into glucose was discovered; the fluid, therefore, contained no ptyalin; it appeared to consist of almost pure mucin.

It might be argued that the contents of this ranula may have come from a salivary gland, but have been so long in the cyst as to have become inert. If it had been originally saliva, great condensation must have occurred, and it might therefore be expected to have been made more active than usual. Moreover, these ferments do not lose their activity when kept for very long periods. A glycerine extract, for instance, remains active for an indefinite period.

It seems probable that the cyst in this case was due to the distention of one of the sublingual mucous glands.

Tubercular Ulceration of Intestine.

At a recent meeting of the Manchester Medical Society (*British Medical Journal*) Dr. Simpson showed the lungs and a portion of intestine from a case of tuberculosis. The interest lay chiefly in the close resemblance to typhoid fever. The patient, aged 21, was admitted to the Manchester Infirmary, November 17th, 1881. The health had been good up to six months before. Since then she had felt increasing weakness, but became much worse three or four weeks before admission, with cough and expectoration. Evening temperature was 101; pulse 128. There were morning remissions. Slight flattening, with diminution of resonance and some moist *râles*, existed at the left apex. Sonorous and cooing rhonchi and moist *râles* were heard, indeed, over the greater part of the chest, but the latter were constant at the left apex. The abdomen was natural, not tumid. There was no pain nor gurgling on pressure in the iliac fossa; but a few rose spots, exactly like those of typhoid, were scattered over the surface. The tongue was a little furred, but moist. The bowels were

slightly confined. The spots appeared and disappeared in successive crops through the whole course of the case. There was high temperature in the evenings, with morning remissions. On November 27th diarrhœa set in, and the motions speedily assumed the "pea soup" character. The expression, the mental hebetude, the character of the delirium, all closely resembled what is seen in typhoid. She died on December 18th. Both lungs were congested at the bases. A small cavity, of the size of a walnut, was found at the left apex; while numerous miliary nodules were scattered through the surrounding lung tissue. In the middle lobe of the right lung was a caseous mass, of the size of a filbert, with some scattered miliary tubercles. The peritoneum was normal, and also the mucous membrane of the ileum till near the lower end, where numerous small, rounded and oval ulcers were found. Their margins were thickened; the floor was formed by the muscular, and in some cases the serous coat, but there was no perforation. The ulcers extended transversely round the intestine, contrasting markedly with those found in typhoid. They extended through the whole length of the large intestine. The other organs were healthy.

"A Flesh Worm."

The following case is reported in the *Medical Press and Circular*, April 5th, 1882, by Dr. W. M. Whittaker. A girl aged 12, thin, pale, and delicate, was brought to me November 25th, 1880, with the following history: Two or three months previously a swelling about the size of a pigeon's egg appeared on the outer ankle of the right foot, causing her some pain and uneasiness in walking. By degrees this tumor slowly moved up the leg and thigh, toward the body, and thence to the right axilla. From this it traveled to the right elbow, then back to the axilla, the right breast, and finally to the back of the neck on the right side. In this situation a small dark spot appeared in the centre of the tumor, which then subsided, leaving in its place a small welt. The dark spot developed into a small orifice, and the girl, upon pressing the welt, gave exit to a grub, along with some semi-purulent matter. A few days afterward a swelling similar to the first appeared a short distance from the place last named, and again disappeared, leaving behind it a welt as before. To the touch, it felt as if there was a piece of whipcord coiled under the skin, in the subcutaneous cellular tissue. Pressure on the little swelling forced out a white grub, about an inch in length, annulated and alive. The girl said she expected the tumor would next appear somewhere in the sternal region, as she could generally tell, by an uncomfortable or sore feeling, whereabouts it was likely to appear. On December 3d she returned, and informed me that the swelling did appear, a day or two after her last visit, in the lower part of the sternum, from which it traveled to the right axilla and thence to the inferior angle of the right scapula, where it presented the usual phenomena. No cause could be assigned. All the other members of the family are healthy, and the girl enjoyed good health up to the appearance of the first tumor. As long as she was under observation, the phenomena occurred every few days. It may be noted, as a curious fact that all throughout only the right side of the body was affected. The two specimens of grub were submitted to some zoölogists, who were unable to give any definite information, beyond assigning the larva to the dipterous order of insects. The largest was 9 mm. in length, and about 2 mm. in breadth.

Sewer Gas and Puerperal Septicæmia.

Dr. John C. Ferrier reports the following cases in the *British Medical Journal*:—

Case 1.—A multipara was delivered at full term; labor normal. A few hours later she was a little feverish. The next day she had headache and slight abdominal pains; temperature 102.2° F. She continued ill for more than five weeks, with symptoms of blood-poisoning. The temperature was sometimes very high, over 105° on one occasion. After the illness had lasted a few days, she had pleurisy on the left side; and toward the end of the attack abscesses formed in the axilla, groin, labia and gluteal region. There was no sore throat and no pelvic inflammation. She recovered. Two or three weeks before her confinement the trap of the water closet became blocked, and while directing the removal of the obstruction she got a strong whiff of sewer gas and exclaimed at the time that she was afraid it would give her diphtheria. She had been feverish and ill for a week before confinement, and her husband said that she "felt so hot in bed that he was obliged to move away from her." There was no history of exposure to any other poison than sewer gas. In the same house, two years before, several of her children had diphtheria, from defective drains, but these were put to rights, and there was no further trouble until this last stoppage.

Case 2 presented much the same history as Case 1. There were no abscesses; severe rigors nearly every day; one wrist joint became red and swollen. Milk was secreted for some time

and required belladonna to stop it. She died one month and six days after confinement. There were no cases of infectious diseases in the house, nor could any fault be found with the sanitary arrangements. But a short time before her illness she had noticed a strong smell from a sewer when out walking.

Dr. Ferrier concludes by saying that there was nothing in the history, symptoms or progress of either case to lead him to suspect that any other poison than sewer gas had been at work.

Epulis, with Profuse Hemorrhages.

In the *Lancet*, Mr. J. W. Hulke, reports the following case:—

A little blonde machinist, aged sixteen, with wax-like pallor, and scarcely able to stand without support, was admitted into Queen's ward on the night of July 29th, 1880, on account of very profuse hemorrhages from the mouth. Their source was a small epulis of the size of a Spanish nut, springing from the interior plates of the alveolar process opposite the right first molar tooth. The girl said that this had begun to grow three years before, soon after she had had an upper double tooth removed at the Dental Hospital. Until this uncontrollable bleeding, which obliged her to come to the hospital, she had not attached any importance to the lump, particularly as it occasioned her but little inconvenience. This molar was drawn, the epulis cut away, and the bone to which it was attached was gouged out. Bleeding, which was somewhat copious, was checked by a compress, dusted with powdered persulphate of iron. The wound healed in about a fortnight, by which time she had begun to lose her pallor. A few months since there was no appearance of a recurrence. The anatomical structure of the tumor placed it in the class of fibro-sarcoma.

Intermittent Fever and Quinine Hypodermically.

In the *Lancet*, March 11th, 1882, Dr. P. A. Smith contributes the following case: A sailor, aged 32, had been sick for three months, with continuous quotidian fever and scurvy. On the day after his admission into the hospital it was deemed advisable to test the statements he had made as to his febrile condition, by allowing him to remain in bed and giving no medicine. At 8.45 A.M. he felt cold, and at 9 A.M. his temperature in the axilla was 102° F., and at 11 A.M., 104°; after which there was a gradual decrease every half hour until 1 A.M. when it was 100.4° F. He was ordered a hypodermic injection of six grains of quinine at 8 P.M., to be repeated at 8 the following morning. It was reported the next day that he passed freely and without fever through the usual times of having the paroxysms. There was no increase of temperature and no uneasiness, and he says this is the first time he has been free from fever for the past three months. He had two injections at the same hours on the two following days, when it was noticed that the arm where the injection was given was somewhat tender, and the quinine was given by the mouth, dissolved in tartaric acid, which mixture was continued in diminishing doses for the next fourteen days. He daily gained in strength, and left, three weeks after admission, in excellent spirits. No slough or abscess marked the site of the injections, and the pain experienced at the time of injection was slight and soon passed away.

Therapeutic Action of Larkspur.

M. Benvenuti, in a memoir analyzed in the *Annales de Dermatologie*, recommends very strongly, a decoction of the flowers of larkspur (delphinium), or preferably an infusion made with four parts of the flowers to 100 parts of vinegar, against the pediculi of the pubis. Two bathings with this liquid have constantly sufficed to destroy the insects and their eggs, without inducing any irritation of the parts to which it is applied. M. Benvenuti has also found it an excellent dressing in ulcerated bubo, having a beneficial effect when carbolic solutions, tincture of iodine and iodoform had been used without result.

As the acetic infusion seems to determine slight tumefaction of the integuments, he found that three grains of the dry flowers, macerated for thirty-six hours in 100 grams of water, yielded a strongly colored liquid, which answered better for all purposes.

Fibrous Tumor Growing from Sacrum.

Mr. Francis V. McDowell reports the following case in the *Medical Press and Circular*:—

M. B., aged 45, presented herself at the Baltinglass Infirmary, suffering from a large tumor growing from the region of the sacrum, which caused her much pain and inconvenience, as she was unable to sit or lie down. The tumor sprang from the external surface of the sacrum, opposite to the promonotory of that bone. There was no evidence of fluctuation, and it seemed to be hard and firm throughout; it had a broad base, and appeared to be deeply attached to the bone. The

growth had been increasing in size very rapidly, and as the woman was anxious to get rid of it, it was decided to remove it. The woman was etherized ; a long incision made over the summit exposed the fibrous nature of the tumor. The only difficulty was in dissecting it from its base, owing to the firm and dense attachment to the bone. Having completely removed the growth, the parts were brought together and dressed with carbolic oil. Some pain and numbness was experienced in the lower limbs for some days, but this entirely passed away with the healing of the wound. The woman made a rapid recovery, and was discharged from the Infirmary three weeks after the operation.

Action of Aconite.

In the *British Medical Journal*, Dr. Edward J. Tilt says that aconitine has attracted so much attention of late, that he will mention the following: A highly nervous lady, at the change of life, suffered from neuralgia. One or two attacks occurred about every week, when the pain was very severe. Six leeches applied to the temple shortened the attacks ; going out of town kept them in abeyance, once, for six weeks ; and the only medicine that did the same was aconite. She used the tincture of aconite, in an aromatic infusion, for sixteen weeks, beginning with five drops, and gradually increasing until she took twenty-five drops, three times daily. That one caused so great a sense of fullness in the throat that it was reduced to twenty, which caused only slight physiological effects. It kept off the attacks for two, three, and once for four weeks ; but it did not in the least diminish their intensity, therefore it was discontinued. The Doctor had every reason to believe that the tincture was a reliable one, and could only account for the tolerance of such enormous doses by some idiosyncracy of the patient. It would be dangerous in the extreme to make a common practice of exhibiting such large doses.

Special Reports.

No. IV.—ADULTERATIONS (Concluded).

WATER.

Professor W. L. Dudley, of Cincinnati (Cincinnati *Lancet and Clinic*), delivered an address before the Cincinnati Medical Society, on the action of water on lead pipes, from which we extract the salient points. He presented no new features, but gave a résumé of existing knowledge.

In nearly every house in all large cities the water which is used for culinary and bathing purposes is conducted through lead pipes, yet how few are they who suffer from lead poisoning; and why? Is it because the water has no solvent action on the lead? Is it because the water is not allowed to remain in contact with the lead for a sufficient length of time? ; or, is it because the water contains such impurities as precipitate the small quantity of lead which may dissolve? These are the questions with which we have to deal. A few months ago, a gentleman came to me with a sample of water, which he said his family used for bathing purposes, and that his child had suffered from peculiar symptoms indicative of lead poisoning. He, therefore, desired an examination of the water. On questioning, it was found that the water was rain water, which had been collected in an ordinary cistern and pumped into a tank, lined with lead, from which it was circulated for use. The tank was filled each night and emptied during the following day. In giving him instructions as to the manner of collecting the sample, he was told to empty the tank that night completely, fill it with water, and the next morning draw off about a gallon, into clean, well-stoppered glass bottles. The quantity brought was 3700 cc., which was evaporated on a water dish to 100 cc. ; a few drops of nitric acid were then added, the solution filtered, and saturated with hydrogen sulphide. A slight dark brown precipitate formed, which proved to be lead. The quantity was small, but sufficient to condemn its use. This water fell in a comparatively pure atmosphere, not contaminated by the smoke, carbonic acid gas, etc., from the city. It was allowed to stand in the tank only twelve hours, and yet contained an appreciable quantity of lead. The first question that arises is, does *pure* water dissolve lead. Prof. W. R. Nichols states that "perfectly pure water, in the absence of air, has no action on metallic lead ; if, however, lead be immersed in rain water, or in ordinary distilled water, there is almost immediate action ; and if, after a lapse of a few minutes, the liquid be agitated, there will be seen an abundance of white scales of the hydrated oxy-carbonate of lead. This violent action seems to be due, in some measure, to salts of nitrous acid, always present in such water, and to be effected by the formation of some nitrous compound of lead, which is more soluble in water than the oxy-carbonate. The salts of lead vary in solubility in water ; one part of the sulphate requires 20,000 parts of cold water to dissolve it, the car-

bonate 50,000; the oxy-carbonate is but slightly soluble, the phosphate is altogether insoluble, the sub oxide is insoluble, the hydrated oxide is soluble in 7000 to 12,000 parts of water, the chloride in 135 parts, and the nitrate in about 3 parts of water at ordinary temperature.

Rain falling in the purest atmosphere will inevitably contain some organic matter, nitrates, and ammonia. In consequence of this class of impurities, the water has a much greater solvent action on the lead than that which contains sulphates, carbonates, and phosphates, and it is on account of this fact that we are saved from serious poisoning by hydrant water. It will be well, therefore, to avoid lead pipes when using pure rain water; when the water is from a well, stream, lake or pond, which contains considerable quantities of carbonates or phosphates, it is perfectly safe to use lead. It would seem that great caution must be exercised in the use of water. It is so liable to impurities of various kinds that it would seem almost impossible to be sure that you had it pure. Therefore, no matter how good, and sweet and pure you may *think* your water supply to be, it is a rule that ought to be never neglected, to filter every drop of water used for drinking or culinary purposes.

WINES.

Even wines are adulterated. We are all familiar with the adulteration process in the manufacture of whisky, gin, and the like, but we now note, from the "*Druggist*," the following "*doctoring*" of wines:—

Sleeman's Circular for February says that the French Government has just passed a most salutary measure, which will have for effect the diminution, if not the complete suppression of the process known as *plâtrage*, now become an almost constant custom through most of the wine districts of France, and which, from having at first been performed on a very moderate scale, has lately enormously increased till it has developed into a crying abuse. The *plâtrage* is carried on during the fermentation, and consists in merely sprinkling the grapes, as successive baskets of them are emptied into the fermentation vats, with plaster of Paris—calcium sulphate—(French *plâtre*), mineralogically known as gypsum or selenite, in fine powder. Now, the grape-juice contains several salts of potash, among which the most abundant are the tartrate and bitartrate, and these decompose when placed in contact with the calcium sulphate, forming calcium tartrate, an insoluble salt, and potassium sulphate.

In the case of potassium bitartrate, potassium bisulphate is formed.

Now, besides the salts of potash above named, the juice of the grape contains grape sugar, a nitrogenous fermenting principle, and an astringent principle, to which latter new red wines owe much of their hardness, and also a red coloring matter with which the astringent principle is intimately associated. The fermentation splits up the grape-sugar, as it is well known, into carbonic acid which escapes with effervesence, and alcohol, which remains dissolved. In pure undoctored wines, in proportion to the development of alcoholic strength, and as the wine by age tends to become more acid, potassium bitartrate separates as a crystalline precipitate, forming the chief constituent of the deposit in the casks known as lees, or when it forms in bottled wines, as the crust.

Now, the astringent principle, which in the red grape is, as we have explained, intimately combined with the coloring matter, seems to be held more or less in solution by the tartrates, and as these subside with age the wine grows less harsh, losing at the same time much of its color, and is said to ripen or grow mellow. As the astringent principle, however, disappears, the wine, if it be one of the weaker French wines, tends to run to the acetous fermentation, and this is why we frequently find a wine become sour and unpalatable shortly after it has mellowed with age and arrived at its maximum of perfection. Many a bin of valuable claret or Burgundy has thus suddenly surprised and disappointed its possessor, changing, in the short space of a few months, from fine mellow wine to undrinkable vinegar.

Now, as stated above, calcium sulphate (*plâtre*) decomposes the potassium tartrates, and by withdrawing them and substituting the potassium sulphate, tends to prevent much of the coloring and astringent matter from passing into solution, so that this so-called plâtrage is nothing more than a means employed by the Bordelais and Burgundians for giving to their wines a fictitious effect of age; and they naturally defend a practice which enables them to bring their wines sooner into the market, economizing their outlay in casks and diminishing the chances of loss entailed by keeping a large stock of wine on hand. Further, the process lends itself to fraud, permitting the wine merchants of Bordeaux and Burgundy to import the strong, harsh wines of the north of Spain and the southeast of France, which, when blended with the small, poorer wines of the hill districts of their own country, and then being *plâtrés* (that is, agitated with powdered calcium sulphate) become mild and palatable. Thousands of hogsheads of wines thus blended and doctored, are annually sold, and too often at the high rates commanded by pure vintage wines.

Under the provisions of the new Act, no wine is allowed to be brought into commerce if it contains over 30 grains of potassium sulphate per litre. Even this proportion is too large. Plâtrage should be entirely prohibited; but when we consider that wines are now often sold with 75 to 90 grains of this salt to the litre, it was time, indeed, that some measures should be taken. The merchants defend themselves on the basis of the practice being innocuous, and that, while it promotes the keeping qualities of the wine, even 60 grains of potassium sulphate could do no harm. It is the greatest possible mistake to fancy that plâtrage makes wine keep; for, on the contrary, it withdraws from it the as-

tringent princip'e, a most potent means of its preservation. For a Bordeaux merchant to contend that forty grains of potassium sulphate to the pint of wine is not or cannot be unwholesome, is a thesis which may be agreeable to his pocket, but certainly ought to be discouraged, for, to say the least, it would be prejudicial to the stomachs of delicate or dyspeptic consumers. Not very many years since a case occurred of actual death by poisoning, by the administration of a comparatively small dose of potassium sulphate, and this salt is well known in medicine as a drastic and dangerous purgative. We should, then, be most sincerely grateful to the French Minister of Commerce for the prudent forethought with which he has protected the consumers of French wines from a practice which has grown into a crying abuse, and for giving us one more guarantee for the purity of these wines, justly ranked as the most esteemed that the world produces.

The *British Medical Journal* says that a wine merchant of Salzburg was recently charged, before the police court at Frieburg, with adulterating wine. It appeared that he had purchased 3000 hectolitres of wine, which, before again selling it, he had increased to 52,000 hectolitres, by means of potato sugar, alcohol, wine dregs, and salt in large quantity. This mixture he sold at a price from three to five times the real value. He was condemned to two months' imprisonment and a fine of $125.00.

FUSIL OIL IN ALCOHOL.

The *Druggist* says that MM. CAZENEUVE and COTTON propose as reagent a solution of potassium permanganate, containing 1-10th per cent. of the dry salt. The permanganate at ordinary temperature is reduced slowly by vinic alcohol, but instantaneously by methylic alcohol. If to 10 cc. of alcohol at 20° there is added 1 cc. of the permanganate solution, twenty minutes are required before the liquid takes the yellow tint indicating complete reduction. If 10 cc. of alcohol are used containing 1 cc. of methylic alcohol, the yellow tint is instantly obtained with potassium permanganate.

CORRESPONDENCE.

Specific Treatment of Zoster.

ED. MED. AND SURG. REPORTER:—

In a recent number of the Buffalo *Medical and Surgical Journal*, Dr. John Boardman, of Buffalo, reports a case of "shingles" cured by the following:—

℞. Ac. carbol., ℥ij
Ol. oliv., ℥j. M.

SIG.—Rub well on the parts, two or three times daily.

After the second application, the burning of the parts ceased, and in a week the patient was well, only a few dry scales remaining.

Some three years ago I commenced the treatment of zoster with carbolic acid, and have successfully treated every case which has since fallen into my hands; I have come to the conclusion that it is as nearly a specific as is sulphur for scabies. I will relate one case, illustrating my mode of treatment.

July 23d, 1881, Mrs. G. called upon me for a prescription for her hired girl. From her description, I guessed it to be a case of erythema, or rhus poisoning, and sent her a solution of plumb. subacetat., for external application, and tr. fer. chlor. internally.

July 25th, was called to see the girl. Found a fine, healthy looking lass of about twenty. On examination I found an extensive crop of patches of vesicles, extending from the interscapular space over the right scapula, through the axilla, on the superior aspect of the upper arm, and on the inferior aspect of the right mamma. In fact, as beautiful a case of shingles as I have seen in a practice of thirty five years. The characteristic neuralgia was unusually severe. Of course, the lead lotion and iron drops had done no good. I immediately commenced my specific treatment, as follows:—

℞. Acid carbol., ℥j
Ung. hydrarg. nit., ℥j. M.

SIG.—Apply freely to the diseased surface, twice, daily.

Cover with cotton batting and over this oiled silk.

Internally, parvules iodide of arsenic, gr. $\frac{1}{100}$, two every two hours.

July 27th. Found smiling faces on both maid and mistress. Pain and burning all gone; eruption arrested and fading. Relief was experienced shortly after the first application. No further trouble was experienced, and in a week more not even a dry crust remained of this heretofore intractable disease.

A stronger ointment may be necessary in an obstinate case, and no harm or injury would be likely to arise if used of double the strength.

Carlton, N. Y. T.R. BAMBER, M.D.

Questions on Vaccination.

ED. MED. AND SURG. REPORTER:—

On looking over the contents of the REPORTER for December 31st, 1881, I find "Questions on Vaccination, by E. M. S." Turning over and reading the article, I fail to see a single question (except to an outsider), on the subject of vaccination.

While I am a firm believer in vaccination and the good therefrom, may I be allowed (if not detrimental to the cause) to ask a few questions?

Is vaccination, when thoroughly done, a preventive against the ravages of small pox?

Is this foul disease being wiped from the face of the earth by vaccination? Or, is it, like other fatal diseases, gradually growing less severe and fatal by natural causes and by good hygienic and

quarantine measures? Is it a boon to the human race? Or, is it a fallacy that will crumble by time and investigation, like homœopathy, calomel and blood letting? Has vaccination contaminated the blood of this and preceding generations, and done more harm than good? Did not varioloid have an existence before Jenner ever saw a cow?

Has vaccination all the prophylactic powers it is represented to have? Do not individuals and peoples have smallpox who have been thoroughly vaccinated? Do not individuals and peoples have smallpox who have previously had varioloid and smallpox? Do not individuals and peoples resist its influence without vaccination? Does vaccination destroy that virus in the system that smallpox has an affinity for, or change that germ in the blood, or change or have an indelible impression on the blood disc, or impregnate a prophylactic into the circulation which will modify or resist its influences?

Is disease, or has it ever, been transmitted by vaccination? Is bovine virus better than human virus? Did you ever know a mare or cow to have syphilis and other transmissible diseases? And are you sure that bovine virus will not or cannot contaminate the human blood? (Or, as Prof. Meigs would put it, the endangium?) Was Jenner a fanatic, and like all fanatics, governed wholly by imagination, without thorough investigation? Have you ever questioned this popular belief? Are not some physicians getting somewhat skeptical? Is not smallpox an epidemic or endemic, like diphtheria and kindred diseases, and, like them, have its run in particular localities, regardless of vaccination? Can you explain why it attacks one community and not another, both being equally exposed and vaccinated? Are not certain localities susceptible to it, and others not? Have not certain districts in Germany had compulsory vaccination for many decades, and still have the smallpox?

The freedom from this scourge in certain localities, is it not due to cleanliness and intelligence? Would not some other counter irritation or some other eruptive disease be as good a prophylactic as cowpox?

Who can compute the amount of money expended for vaccination? Has there not been enough expended to clothe the paupers of every clime? Have not physicians vaccinated because their preceptors did it, and because it was popular to do so? Have they ever dreamed of making investigation for themselves?

Was it not contended *at first* that vaccination was a prophylatic for a lifetime, then for seven years, then for only a few years, and now that it is better to vaccinate every year. And after awhile will we not have to vaccinate twice a year in order to have a sure thing; or wear a scab on our arm the year round, and be called a generation of scabs?

Is not smallpox more general over the face of the earth at the present time than it was ever known to be, notwithstanding the people's years of vaccination? Will it ever be exterminated, any more than other diseases? Are we to swallow this because the authorities say so? Or, can we prove it, beyond a doubt, to be a blessing to the human family?

These are questions to be weighed carefully, wisely, promptly, fearlessly, and conscientiously.

Sioux City, Iowa. G. W. Beggs, M.D.

News and Miscellany.

American Medical Association.

Philadelphia, 1400 Pine Street.

The Thirty third Annual Session will be held in St. Paul, Minn., on Tuesday, Wednesday, Thursday, and Friday, June 6th, 7th, 8th, 9th, 1882, commencing on Tuesday, at 11 A.M.

"The delegates shall receive their appointment from permanently organized State Medical Societies, and such County and District Medical Societies as are recognized by *representation in their respective State Societies*, and from the Medical Department of the Army and Navy, and the Marine Hospital Service of the United States."

"Each State, County, and District Medical Society entitled to representation shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for every additional fraction of more than half that number: *Provided*, however, that the number of delegates for any particular State, territory, county, city, or town shall not exceed the ratio of one in ten of the resident physicians who may have signed the Code of Ethics of the Association."

☞ Secretaries of medical Societies as above designated are earnestly requested to forward, *at once*, lists of their delegates.

SECTIONS.

"The Chairmen of the several Sections shall prepare and read in the general sessions of the Association, papers on the advances and discoveries of the past year in the branches of science included in their respective Sections. * * *"—By-Laws, Art. II, Sect. 4.

Practice of Medicine, Materia Medica, and Physiology: Dr. J. A. Octerloney, Louisville, Ky., Chairman; Dr. D. J. Roberts, Nashville, Tenn., Secretary.

Obstetrics and Diseases of Women and Children: Dr. H. O. Marcy, Boston, Mass., Chairman; Dr. C. V. Mottram, Lawrence, Kan., Secretary.

Surgery and Anatomy: Dr. —— ——, Chairman; Dr. W. A. Byrd, Quincy, Ill., Secretary.

State Medicine: Dr. A. L. Gihon, U. S. Navy, Chairman; Dr. J. H. Sears, Waco, Texas, Secretary.

Ophthalmology, Otology, and Laryngology: Dr. —— ——, Chairman; Dr. J. Solis Cohen, Philadelphia, Secretary.

Diseases of Children: Dr. S. C. Busey, Washington, D. C., Chairman; Dr. Wm. Lee, Baltimore, Md., Secretary.

Dentistry: Dr. D. H. Goodwillie, New York City, Chairman; Dr. T. W. Brophy, Illinois, Secretary.

☞ A member desiring to read a paper before any Section should forward the paper, or its *title* and *length* (not to exceed twenty minutes in reading), to the Chairman of the Committee of

Arrangements, at least one month before the meeting.—*By Laws.*

Committee of Arrangements: Dr. A. J. Stone, St. Paul, Minn., Chairman.

Amendments to the By-Laws—

Offered by Dr. D. H. Goodwillie: Art. II, Sec. 8. Permanent Members; strike out the words "but without the right of voting."

Offered by Dr. J. H. Packard: Regulation II, par. I, to read "as Permanent Members or members by application."

Regulation VI, line 4, strike out 5 and insert 10. Second paragraph, lines 4 and 5, strike out all after "publication" to and including "Association," and insert "publication."

Regulation IX. Add new paragraph: Members by application shall consist of such members of State and county societies, in good standing, as shall make application in writing for admission. They shall simply have the right to receive the Journal on the same terms as other members."

Regulation IV, paragraph 6, strike out all from "see," in line 8, to "and" in line 9.

Regulation V, paragraph 3, after "published" insert "in such manner as the Association may direct." WILLIAM B. ATKINSON, M.D.,
Permanent Secretary.

Pennsylvania State Medical Society.

All delegates and others intending to be present at the meeting of the State Medical Society are requested to so notify Dr. Wm. Varian, Chairman, Committee of Arrangements, Titusville, Pa.

A Rebuke to the New York State Medical Society.

The following resolutions were adopted by the St. Louis Medical Society, April 1st, 1882:—

Resolved, That the St. Louis Medical Society, while it desires to accord the broadest freedom to medical investigation, and recognizes fully the right of individuals to form and hold private opinions, hereby declares that it regards with disfavor any steps taken to lessen or obliterate the distinctions and safeguards between an honorable practice of medicine founded upon science and that founded upon any of the current delusions and exclusive medical systems of the day.

Resolved, That a copy of this resolution be forwarded by the Corresponding Secretary to the New York State Medical Society, to the Permanent Secretary of the American Medical Association, and to several specified Medical Journals.

WM. DICKINSON, M.D., *President.*
A. H. OHMANN-DUMESNIL, M.D., *Rec. Sec'y.*

Philadelphia County Medical Society and Homœopaths.

At the stated meeting of the Philadelphia County Medical Society, held April 19th, 1882, the following resolutions were adopted:—

Resolved, That this Society reaffirm its adherence to the principles of the Code of Ethics of the American Medical Association, and declares that, in its opinion, for a physician to extend professional recognition to irregular practitioners, is to patronize and encourage irregular practice; and is alike inconsistent with honesty of purpose and the pursuit of medicine as a science.

Resolved, That this resolution be referred to the Pennsylvania State Medical Society, at its next annual meeting.

Another New Congress.

It has been resolved to call together a "Congress for Internal Medicine," to convene next April, at Wiesbaden. Professor Seitz has undertaken all the preliminary steps relating thereto.

Items.

—A chair of Morphology is to be established in the University of Cambridge.

—At a meeting of the Royal College of Physicians of London, on Monday, April 3d, Sir William Jenner was unanimously re-elected President of the College for the ensuing year.

—The Germantown *Telegraph* is responsible for the following: A country physician of limited sense and "limiteder" education, was called to see Mr. R.'s little boy, who was quite ill. He gave some medicine and left, promising to call on the following morning. When he arrived Mr. R met him at the gate and informed him that the child was convalescent. "Convalescent?" said the doctor, "convalescent? Then if he is that bad off you'll have to call in some other physician; I never treated a case of it in my life!" and with that he mounted his horse and departed.

QUERIES AND REPLIES.

Subscriber.—Formula for Infusion of Golden Seal. Take of golden seal, bruised, one troy ounce. Boiling water, a pint, macerated for half an hour in a covere vessel, and strain.

A. McM.—Cuticura ointment is a secret preparation, and we do not know its constituents.

A. O. S., Pa.—The strength of the nitrate of silve solution is given, in the article you refer to, as *a 30 per cent. solution*—which means a solution of 1-30.

J. N. R, Pa., asks whether any of our readers have ever heard of twins living to maturity, and both having families.

MARRIAGES.

BRINCK—BRAMAN.—In New York, on Tuesday, April 18th, 1882, at the residence of the bride's mother, by the Rev. Dr. John Hall, Dr. William Brinck and Adelaide, daughter of the late William H. Braman, all of that city.

GLADISH—OPPELT.—On Wednesday morning, April 12th, at the bride's residence, in Loogoo ee, Ind., by Rev. W. H. Shaw, Mr. J. W. Gladish, Attorney-at-Law, of Petersburg. Ind., and Miss Louise A., daughter of Dr. E. A. Oppelt, of Loogootee, Ind.

KIRBY—HILTNER.—In this city, on Thursday afternoon, 20th inst., by the Rev. Wm. B. Wood, D.D., at the residence of the bride's mother, No 2220 Oxford street, G. Stewart Kirby, M.D., and Miss Kate Ida Hiltner, both of this city.

PALMER—STANLEY.—At the home of the bride, April 3d, by the Rev. E. H. Boynton, Dr. G. S. Palmer, of Waterville, Mass., and Miss Mary E. Stanley, of China, Ont.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

SIMPLE MITRAL STENOSIS.

BY M. DREYFUS-BRISAC,

Physician to the Paris Hospitals.

Gentlemen:—The discussions which occupied the attention of the scientific world forty years since, regarding the symptomatology of mitral stenosis, and the great divergency of opinions which then reigned concerning its physical signs, are no longer remembered to-day. There was no longer any foundation for this controversy, from the moment it was admitted that simple, uncomplicated mitral stenosis is a rare lesion, being associated almost always with more or less marked insufficiency. As, on the other hand, the distinction between stenosis and insufficiency seems to be but of minor importance in the physiological pathology of the case, since the two lesions follow identical laws in their evolution, practitioners, in the end, no longer attempted absolute precision in a diagnosis of purely anatomical interest, and fell back on the comprehensive and very convenient term of mitral disease or lesion, which was considered sufficiently precise for all clinical purposes.

This opinion certainly corresponds to reality in the great majority of cases, and mitral lesion is the habitual type of "chronic heart disease." Have we not, however, gone too far, in almost denying a place among diseases of the heart to simple stenosis, as has been done in theory, particularly by foreign authors, and in practice by most practitioners?

There has been of late years some tendency toward reaction, commenced by M. Durosiez, in his interesting memoir in the *Archives Generales de Medécine* (1877) and continued in the theses of M. Marshall (1879) and of Marien (1880) both elaborated in Prof. Hardy's service, and though succinct, bringing forward certain clinical particularities which merit careful consideration.

Besides the common double lesion, stenosis with insufficiency, there seems to exist a variety of mitral stenosis which merits special description, particularly as regards its etiology and course. It is true that the elements on which to found such study are as yet, in great part, wanting; but it is none the less interesting to call your attention to certain unexpected results which are in contradiction with generally received opinions.

The etiology of this affection has received most attention. Durosiez had already shown that simple mitral stenosis is much more frequent in females (46 cases in women to 15 in men); this particularity has been confirmed by all the statistics collected in the thesis of M. Marshall, written under the direction of M. Landouzy.

In 100 cases observed by M. Landouzy, 85 were in women and 15 in men; Duckworth, in the St. Bartholomew Hospital Reports, Vol. xiii, says he met with 78 cases in women to 21 in men. The personal observations of M. Marshall show 76 per cent. of the cases as occurring in women. Finally, collecting together all the statistics, we find a percentage of 70 for women to 30 for men.

Although all these researches have not been undertaken with this special object in view, and several authors may have confounded the double

mitral lesion with simple stenosis, it is still plainly evident, from this notable percentage in a large number of cases, that the latter affection is much more frequent among women.

It is true, that many practitioners had already remarked a predominance of the mitral over aortic lesions in women ; but no author had attributed to sex so marked an influence in the development of these alterations.

It may be said in general, that simple, uncomplicated stenosis is an affection peculiar to young women, for it forms no exception to the well-known law that mitral lesions belong particularly to the first period of life.

Very often it dates from childhood ; unfortunately precise knowledge on this point is wanting ; because, evidently, stenosis is more liable to pass unrecognized in young subjects than the other organic diseases of the heart, and it is thus rendered difficult to establish its period of development.

The point the most obscure in the etiology is concerning the influence of rheumatism, and in general, of maladies having a tendency to affect the endocardium, on the production of mitral stenosis.

While Duckworth found rheumatic antecedents in 60 per cent. and Durosiez in 50 per cent, of his cases, other authors, and particularly Hilton Fagge (Reynolds' System of Medicine), Landouzy and Marshall, admit, with Grisolle, that mitral stenosis is oftenest developed slowly and insidiously, without any possibility of demonstrating at any period the existence of rheumatism or arthritic manifestations.

We should incline willingly to this conclusion, but with great reserve, for nothing is more frequent than slight and incomplete manifestations of rheumatism in childhood, from simple chorea to torticollis or pulmonary congestion.

On the other hand, it is evident that the infectious diseases, the eruptive fevers particularly, may have some part in the etiology of mitral endocarditis.

Such a lesion may remain for years latent, being slowly organized, and yet have its source in one of the maladies common during childhood.

But extremely little is known concerning the influence of the different fevers, particularly of typhoid fever, in producing heart troubles.

It is at any rate certain that the primary causation or pathogenesis of mitral stenosis remains obscure ; for in what manner can be explained the incontestable predisposition of females to this affection ? We naturally seek the solution of this problem in the anatomical and physiological conditions special to women, and are led to incriminate either pregnancy or menstruation.

If it be true, as has been shown by Durosiez, that the morbid phenomena are oftenest observed after pregnancy, there is no proof that this condition has had any part in producing the cardiac alteration ; ordinarily pregnancy only accentuates a lesion which up to that period has remained latent.

As regards the explanation put forward by M. Marshall, it does not seem entirely without foundation.

"The predominance of mitral stenosis in women, she says, may be due to the comparative narrowness of the left ventricular orifice and to the composition of the blood, which is, in all probability, peculiar during the period of sexual activity."

In this theory, the assimilation of the blood of females, during the period of genital activity, to that of rheumatic patients, on account of its deficient alkalinity, must be regarded as more than hypothetical.

The anatomical consideration invoked by M. Marshall has greater weight. Bizot has, in effect, demonstrated that the mitral orifice, under normal conditions, is narrower in women than in men ; whence exaggeration of blood pressure at this point, which consequently becomes a place of election for inflammatory and degenerated alterations.

This peculiarity is the more interesting, as stenosis of the aorta, close to its cardiac origin, is also more frequent in females, a fact on which Virchow founded his theory of chlorosis.

If this last affection is, at least, in part, of congenital origin, yet remaining latent until the period of puberty, why should not the same thing happen for this variety of stenosis, which has many points of resemblance with chlorosis ?

It is generally admitted that mitral stenosis cannot long pass unperceived ; that its existence is early shown by functional disorders, which draw attention to the condition of the heart, and finally that it rapidly gives rise to asystolic manifestations. Death, according to generally received opinions, supervenes in a few years, six or seven at the furthest.

Is not this picture more sombre than reality, particularly as regards uncomplicated stenosis ? and, on the other hand, is it always possible to recognize the organic alteration with such facility ?

Many clinical observations show that the lesion may remain many years latent or give rise to but slight and fugacious derangements, such as slight dyspnœa on exertion, palpitations, epistaxis

(Durosiez), all phenomena common among young, healthy girls at the period of puberty.

Often, it is true, the signs of pulmonary trouble are more marked; there is a tendency to bronchorrhea, with slight but repeated hæmoptysis, which call attention to the state of the heart. But even under these conditions how frequent are the errors of diagnosis.

At the début of the sexual period in young girls, the menstrual flow disappears entirely for several months, or is frequently obstructed; the patient becomes pale, takes on a chlorotic appearance, is easily put out of breath, catches cold at the slightest change in the weather, and often complains of abundant expectoration; when, then, in connection with all these symptoms, hæmoptysis appears, the attending physician necessarily thinks it is the début of tuberculosis. Auscultation of the lungs reveals here and there foci of fine râles, while physical examination of the heart remains almost negative, the signs observed being so slight that they are considered to be simply functional, and due to the neuropathic condition of the patient.

Thus is constituted, to use the expression of M. Germain Sée, a latent cardiac affection, of either dyspnœic or hæmoptoic character, and the young girl, who, for that matter, presents hardly any of the general symptoms of heart disease, is for years treated for tuberculosis.

For, notwithstanding all the entirely theoretic considerations of pathological physiology, which deny any durable compensatory action to the left auricle, this latent period may last a long time if no perturbing medication be instituted.

But this state of equilibrium, necessarily unstable, will be broken, and things take on an entirely different appearance, from the moment the heart is accidentally overworked.

Such is the case for men of dissipated habits or exercising a fatiguing profession; and thus may undoubtedly be explained the greater gravity and the more rapid progress of the disease in men.

Such is particularly the influence of pregnancy; many of the cardiac symptoms observed at this period, and generally attributed to functional hypertrophy of the heart, are in reality due to the existence of this form of mitral stenosis, which had remained almost or quite latent up to the period of pregnancy.

From the moment the heart is, as it were, forced, all the general symptoms of mitral disease are successively produced; it is, however, oftenest by intense dyspnœic manifestations, or very abundant hæmoptysis, that the asystolic period commences.

Very gradually the heart dilates, secondary insufficiency is developed, and from that period the double mitral lesion is constituted, with its usual clinical signs. The physician who then sees the patient for the first time can but affirm the existence of mitral disease, without suspecting what has been the course of the morbid process.

This explains how this variety of mitral stenosis has so often passed unrecognized, and why its nosography is as yet imperfectly elaborated.

Communications.

DIABETES MELLITUS.

BY PH. M. SCHIEDT, M.D.

Read before the Northern Medical Association, February 24th, 1882.

At the very threshold of our inquiry we are met with complications, difficulties, and obscurities; and though this disease has been supposed to be known to the ancients, from the first century, and diagnosticated fully by Willis, in 1674 and by Morton, in 1675, yet to-day the subject is all confusion; not even have we arrived at a satisfactory state in nosology; the various authors are as much at variance with their classifications as they are with theories, pathology, and therapeutics.

One will classify this disease as pertaining to diseases of the liver; a second to the diseases of the alimentary canal; a third to urinary affections; a fourth to the nervous system; a fifth to diseases of pancreas; a sixth to the kidneys; a seventh to general or systemic diseases; while still another class do not consider it worth while to make any subdivisions, calling it "accidental," because, as they say, it may occur from injuries, falls, a gouty diathesis, and even that very many old people, by virtue of their decrepitude, are diabetic.

Its etiology and pathology are as dark and obscure as any disease we are called upon to treat. Finally, its prognosis and therapeutics are as discouraging and unreliable as in tuberculosis and carcinoma. At the present enlightened stage of medical literature and science, with all its modern appliances, we are confronted with the question: "What do we know about diabetes?" and the humiliating answer must go forth, from every conscientious physician who is called upon to treat this sometimes very chronic disease, "we know very little." Therefore, it behooves us, as physicians and guardians of health, as well as in the interest of science, and the further advanc-

ment of individual knowledge, to be ever on the alert for what may enhance or seem to enlighten our understanding of this persistent, though not very common, disease; any facts or any line of treatment, or any drug, that seems to offer success should be recorded for our mutual benefit.

For this reason I will now briefly record a case of diabetes mellitus that recently came under my care and observation, where it seems that I was successful in the treatment adopted, with such other remarks and notes as I was able to collect during the short time that has been at my disposal for the preparation of this paper; any shortcomings you will kindly bear with.

On December 3d, 1881, I was called to see Mrs. K., aged 40, who presented the following symptoms:—

She told me that for some time, about three months, she had been feeling unwell; was emaciating frightfully, although she had what she supposed a fair appetite; she felt always fatigued; did not wish to take any medicine, and, in consequence, neglected to send for a physician sooner than when I was called. When I saw her she complained of excessive thirst, profuse micturition, at times accompanied with incontinence of urine, and a burning sensation, having an erythema about the vulva and the meatus urinarius, and some parts of the thigh, accompanied with intense itching, for which she principally called me in. She was peevish, had flushes to the face, had a worn, distressed countenance; her tongue had a dry, red, yet fissured appearance. She had a dry, harsh skin; complained of chilly sensations, and stated that her eyesight was failing. I was furnished with some of her urine, which was slightly colored, resembling water more than urine; its sp. gr. was 1:050, and with several tests gave the reactions of a great quantity of sugar. The urine was sticky to the hand, like molasses. She also passed a large quantity, at first from 10–12 qts. in twenty-four hours. My diagnosis was diabetes mellitus. What could have been the etiology of this case, I was unable to trace.

Etiology.—The etiological data of this disease recorded by the authors seems to be nothing but confusion. It is said that this disease is not known to occur in any other animals but man, and, therefore, Benardt inclines to the theory that it is due "not to the pathological change or disease of the liver, but depends upon the nervous derangement of the liver due to enervation?" It occurs most frequently in adults from 25 to 65 years; the ratio of males is 3 to 1 between 30 and 40, while the same ratio holds good in females from 10 to 30; between 10 to 20 the number of females affected by this disease is greater than that of the males in the same decade, as well as that of the females in the two succeeding ones. It is found more commonly, at a later period, in persons among the higher walks of life, such as private gentlemen, the clergy, lawyers and doctors. It has occurred in very young and in the very old. Griesinger found, in a table of 618 cases, 4 under 10 years, and 16 from 70 to 90. Hereditary predisposition is denied by some, as unfounded in practice, yet some records by well authenticated authors do not admit of any doubt that hereditary influence has something to do with it, even if it only can be traced rarely. While in some cases, parents and children have had the disease, yet the larger part of children *escape it*, or its transmission may pass over in one generation to be found in another. Bouchardat found it in a brother of one of his patients, who had no idea that he was affected. Dr. Prout met it in an uncle, a brother and a sister of the same family; and another family where *seven* had the affection.

It is said that this disease hardly ever occurs in negroes, while it is very common among the Jews; such as are bankers. It is rarely observed in Holland, Russia, Brazil and Central America; its appearance is very much oftener in England, Germany, France, and especially in Scotland and Ceylon. The exciting causes recorded in the books are one mass of multiplicity, yet in very few cases are we able to make them out clearly. Injuries to the head, and especially concussions of the whole body, and injuries of the spinal column; softening and degeneration of the brain or medulla oblongata; excessive mental exertion, grief, depression, sexual excesses and also *sexual continence*, as reported in the Medical and Surgical Reporter, January 21st, 1882, by Dr. H. C. Yarrow. Exposure seems to be a fertile cause, especially during the menstrual epochs. It may occur during pregnancy and lactation, and is said also to arise or follow diseases of the pancreas. Prentis found, in five cases out of nine of fatty degeneration of the pancreas, diabetes mellitus. In cirrhosis of the liver, in phimosis, in intermittent fever temporarily, in impotence and in aged people without any apparent disease. It is also produced artificially in poisoning by strychnia, woorara, chloroform, and carbonic oxide, and in puncturing the floor of the fourth ventricle. Finally, but not least of all, a fruitful etiological source for this disease is undoubtedly intemperance (the bane of civilization and the curse of homes).

Symptomatology.—The brightest feature about this whole subject is doubtless its symptomatology. Though a vast array of symptoms are generally given, yet with a few pathognomonic signs we are enabled quickly to diagnosticate this affection: such are frequent micturition, excessive thirst, rapid emaciation, a dry, fissured tongue, with a urine of high specific gravity, ranging from above 30, from its incipiency, and the response to the chemical tests for sugar. Dr. Roberts says: "If a child is found masturbating suspect diabetes mellitus."

Among the symptoms enumerated by the various authors are excessive thirst, polyuria with painful micturition, voracious appetite, anorexia, rapid emaciation, the red, fissured tongue, with longitudinal streaks along the dorsum, and especially at the edges; sometimes it feels sticky to the touch and appears to the patient as adhering to the palate; the teeth may become loose in their sockets, and the gums are often found spongy and bleeding easily. We often have a dry, furfuraceous skin, even at times intolerable itching, with excoriations about the external genitals; so that if we have pruritus at the external genitals or anal regions, especially in women and children, it behooves us, as Dr. Roberts says, to examine the urine; constipation, with various dyspeptic symptoms, follow in quick succession. They often have chilly sensations at various parts of the body, so that Pettenkoffer and Vail found that diabetic patients lose the power (which healthy persons possess) of storing up oxygen in the body during the night, for utilization during the day. Loss of sexual appetite and power is often noticed; whether due to this or other causes is hard to say. Klebs asserts that in diabetes the liver is universally enlarged. Stock and Frerichs say it is due "to the prolongation or new formation of the secretory cells of the liver." The nervous system seems to be greatly disturbed. We find a peevish disposition, an easily irritated temperament; the memory often fails, and the patient frequently becomes melancholic; cramps are very common, especially at night. We may have hyperæsthesia, and also partial anæsthesia. Trousseau mentions amblyopia, total failure of vision, and cataract; while Brunton speaks of presbyopia and total failure of sight following or complicating this disease. The quantity of urine passed is very largely in excess of its ingesta, sometimes amounting to 80 and 100 ounces per diem; while Dr. S. D. Gross (Diseases of Urinary Organs) has recorded from two to four gallons in twenty-four hours. Aitken says it has reached, in some cases, thirty or more pints daily. Dr. Elliotson, in his Practice of 1844, speaks of a case where it was *fifty-two* pints daily. Its specific gravity may rise as high as 1.040–50, while Bouchardat has seen in one case, recorded by Trousseau, the specific gravity as high as 1.074.

I have used in my case Trommer's, Moore's also the fermentation tests; over night I found the bottle filled by what I presume were the "Tarulæ cerevisiæ." I also used the subnitrate of bismuth test mentioned by Dr. Tyson. I would particularly draw your attention to this test, as it is easily carried out, and seems to be quite reliable. Only a small portion of the bismuth is placed in the tube with the diabetic urine, and boiled for a few moments; if sugar is in the urine we will have a *black deposit* with a black solution, where if there is no sugar it will remain light gray. The only objection I have to this test is the disagreeable odor emanating from it while testing; I do not think that Dr. Tyson speaks of this, and it is unlike anything that I ever perceived before; I am at a loss to what to compare it.

Although pathology of the different diseases has been greatly revolutionized since Virchow, Benhardt, Rindfleisch, and others have become eminent in this branch of science, yet to day the pathology of this affection is still very much shrouded in dark obscurity, and we know not what theory to believe, for the various pathologists are at variance (with each other), and often contradictory. Brunton says, "the presence of sugar in the urine, as an abnormal constituent, has been long known; but the pathological processes which it indicates are only now, thanks to the labors of Benhardt, Czan, Eckhardt, Flint, Gusk, Pavy, and others, beginning to be clearly understood." Even to-day we find diabetes ranged in the text-books as diseases of the kidneys and albuminuria, when we know that these organs are not at fault.

Niemeyer says the theory which holds that "it is due to the alkalinity of the blood, presupposing that the sugar or glycogen is formed *in* the blood constantly, has been disproved." The fermentation theory, which supposes that the excess of sugar is due to the abnormal conversion of amylaceous matter into sugar, he says is untenable.

Dr. McDonnel has advanced the theory that the "hepatic (dextrin) is not converted into sugar, but united with nitrogen to form a new protein compound resembling casein."

Benhardt leans to the prevailing theory of

modern pathology *which attributes the glycogenetic functions to the liver*, where *diabetes* may be due either to *increased introduction of sugar* or *to diminished destruction* of it, or to both of these together, *but adds, that it depends upon the nervous derangement of the liver* (hepatic cells), due to *enervation of the same*, and says "*if it was in our power to galvanize* the *sympathetic nerve, we would have the best treatment of this disease.*

Teherinoff says: "*The liver sugar is not made from the glycogen*, but on the contrary *glycogen is formed from the sugar which arises in the liver.* Hence, instead of glycogenetic (sugar forming) it should be called "glycophthinium" or (sugar consumer). *If the liver loses its capacity to convert the sugar* into "*glycophthinium*," *it remains in the blood and diabetes mellitus follows.*

In Ziemssen's Encylopædia we find the theory that diabetes is due simply to hypertrophy of the glandular parenchyma, when it is probably connected with an increased and accelerated *formation* of glycogen in the hepatic cells. And according to Stock and Frerichs it is due to the swelling of the liver, and that it may also be due to the prolongation of *new* formation of the *secreting cells.*

Niemeyer states that the puncture of the floor of the fourth ventricle does not depend upon functional abnormality of the kidneys, as sugar is not found in them, but is excreted from the blood. I think I cannot do better than to extricate from this labyrinthine confused pathology, what is the resumé in Reynolds' System of Medicine. "Diabetes may arise, 1st, from increased formation of sugar, due to (*a*) excessively rapid digestion of starch or sugar; (*b*) to failure or imperfection in the glycogenetic function of the liver, and possibly to some extent, also, of the muscles; (*c*) to increased transformation of glycogen into sugar, due to accelerated circulation through the liver, or a larger proportion of ferment in the organ or the blood. The circulation may be quickened, either by increase of the general arterial pressure, or by dilatation of the vessels of the liver, and especially of the hepatic artery. Increased blood pressure may be due to muscular exertion, such as occurs in epilepsy, or to contraction of the arterioles, such as is caused by impeded respiration, exposure to cold, cholera, and Bright's disease; the hepatic vessels may be dilated reflexly; irritation applied to the vagus, either at its ends in the lungs, liver, or intestine, in its trunk, or at its roots in the medulla, or to the cerebrum, cerebellum, pons, and probably some of the sympathetic ganglia. They may also be dilated, and the current in them accelerated, by section of their vasomotor nerves at any point between the medulla and the liver, provided that the interspinal vasomotor nerves are not also divided, and the supply of blood so much diminished that no increase in the hepatic circulation follows the section. Increased formation may also occur in the muscles.

2d. Diabetes may also arise from lessened combustion, due either (*a*) to insufficiency of the ferment which should convert the sugar into lactic acid and glucose; (*b*) to an altered quality of the sugar which enables it to resist the action of the ferment, or (*c*) to diminished circulation through the muscles preventing the sugar from coming sufficiently into contact with the ferment.

The therapeutics of this disease seem at present more varied and less encouraging than its mixed up etiology and pathology. From its very inception the treatment has been as varied and empirical as carcinoma and tuberculosis. Many drugs and varied lines of treatment have been used, but none with perfect success. The rich materia medica seems to be powerless and useless against the stubborn chronicity of this affection. Niemeyer and Pavy refer to carbonate of ammonium, bicarbonate of sodium, in from ʒj to ʒiv doses, to opium, belladonna; Roberts mentions codeia in ¼ to ½ gr. doses. Mr. Richardson, of England, speaks of peroxide of hydrogen, of tr. iodine 20 to 30 gtts., also of Fowler's solution from 3 to 30 gtts. Having read that Dr. Da Costa used the fl. ext. of ergot in diabetes insipidus, I thought it would be worth a fair trial in this disease, since no drug seemed to be known up to the present time which could be relied upon. As ergot possesses the power to contract the arterioles of the vascular system, and according to one of the accepted theories, we have dilatation of such, I gave it in fʒss doses three times per diem, and continued it for some time. I found by its use that the specific gravity was reduced within one week to 1.040, its quantity from 10 to 12 qts. to 6 to 8 qts, the thirst diminished, and the itching abated. Thus the improvement gradually and steadily took place until the urine was diminished to 1 to 2 qts. per diem; no thirst, no itching, very little sugar, and patient feels almost like a new being.

In the continued use of ergot for over a period of two months, I found very few manifestations of ergotism. I treated her solely with the ergot, with the exception of some intercurrent remedies to correct existing symptoms. Of course, I am well aware that restriction in diet must be complementary to the use of drugs. Most authors

agree that the best success is attained not by an exclusive diet, either of animal or vegetable food, but a proper restriction of vegetables becomes necessary to prevent glycogen from being continually formed. Vegetables that contain sugar or starch must be prohibited. Meats, fish and poultry should be largely given. Eggs, cream, milk, and some butter. Vegetables, especially such as should be freely partaken of, are greens, spinach, cresses, lettuce and cabbage. No wheat bread, but bran cakes and bread.

I am quite conscious that a single case is no criterion to go by; yet I think the apparent success obtained in this case should be followed by the medical fraternity, and its results frankly recorded, and perhaps the future will show that it may be efficacious.

Remarks and Discussion of Dr. Schiedt's Paper.—Dr. J. B. Walker, referring to the beneficial results obtained in some instances, by the administration of ergot, related the following:

Case 1.—Male, inmate of Blockley Hospital; presented all the ordinary symptoms of diabetes mellitus. Diuresis amounted to 26 pints per diem. Patient was enabled to surreptitiously procure preserves and sweets, and regulation of diet was impossible, yet, notwithstanding this, he improved greatly under the use of opium and ergot, which were administered combined, separately and alone. The ergot was manifestly superior to the opium, and the results such that the patient left the institution considering himself so well as to need no further medical attention.

Case 2.—Female. Two years ago, while sojourning in the country, she received unpleasant news which, in addition to the great anxiety, occasioned marked mental depression. Almost immediately diuresis occurred, amounting to from ten to twelve pints in the twenty-four hours. The tests for glucose responded characteristically. Her skin, instead of the usual harsh, dry character, presented a moist and pliant surface. The bowels were not confined, but moved daily. The treatment consisted in restricted diet and the administration of ext. ergotæ fld., ʒ ss t. d. Marked improvement followed, and the patient passed from under observation almost entirely well.

Case 3 is one of which I have some knowledge, although it was under the care of Prof. Clara Marshall. The detailed history I cannot give, except that all the symptoms of diabetes mellitus were present. The patient was restricted in diet, and the treatment consisted of the exclusive use of opium. The result was everything to be desired, as a complete cure resulted. . . . .

There is no specific remedy for the direful malady, and the treatment must be regulated and depend upon the peculiar determining conditions found in individual instances, as is evinced by the citations just made.

Case 2 probably depended upon dilatation of the cerebral vessels, and, therefore, was ergot especially indicated. Opium probably acts by virtue of its power to exert a sedative influence upon the cerebral centre, and is indicated in cases of nervous excitement, which determines a hyperæmia of the centres.

Dr. J. T. Eskridge exhibited a section from the pons of a patient who died from diabetes mellitus, and another from the pons of a patient who died from general paralysis of the insane. The only noticeable feature consisted in a slight change of form of a few of the nerve cells in each specimen, which probably were the result of the necessary manipulative processes consequent upon preparation. Nothing pathognomonic was discernible.

He also directed attention to latent diabetes mellitus, and narrated an instance of a sudden death, where examination of the urine revealed the existence of glucose in abundant quantity. In reference to the efficacy of ergot, he referred to a case of a girl, ten years old, in whom diabetes insipidus existed. The quantity of urine daily voided varied from ten to fifteen pints. Ergot, in the form of the fluid extract, was administered, and the results so marked that the patient was considered sufficiently improved to abandon further medical advice. In an instance of this disease, far advanced, where vision was so impaired that the patient was only enabled to distinguish day from night, ergot proved absolutely useless. The Doctor is of the opinion that in the early stages of the disease much may be expected from ergot.

Dr. L. Brewer Hall does not feel disposed to admit that diabetic cataract is the direct result of the action of glucose upon the lens, and inclines to the belief that it results from the general adynamia resulting from the disease. He referred to the experiment of producing cataract artificially by injecting solutions of sugar into the anterior chamber, in healthy individuals, but especially directed attention to the difference of true cataract occurring in diabetes mellitus, and the mere cloudiness following the injection of sugar solutions. He also spoke of the excess of fat in the blood, lipæmia, existing in this affection, and mentioned the case reported by Dr. Heyl, of

appearances of the eye ground. The fatty emboli clogging the pulmonary vessels and the fatality resulting therefrom he especially dwelt upon, and desired to impress the Society with the fact that many of the concomitant phenomena too frequently attributed to the direct effects of glucose are often due to fatty emboli which plug the capillaries and impair function. In a case of impaired vision coexisting with diabetes mellitus benefit was derived from the use of full doses of potassium bromide.

Mrs. Dr. Higgens, from the Pacific coast, a visitor, on being invited to participate in the remarks, related instances of several cases occurring in her hospital experience some twenty years ago, when restriction in diet was not enjoined. The cases all terminated fatally, or at least, no cures were noted. A relative, who lost three children in a short time, grieved greatly, and was, in consequence, afflicted with diabetes mellitus. Under the use of valerian and ergot she improved, and finally was cured. Any new trouble, however, was accompanied by a return of symptoms, which always entirely disappeared by the above treatment.

Dr. Wittig, referring to the pathology, believes the kidneys to be the principal seat of trouble. Iron, he considered to be especially needful, when renal hyperæmia constitutes an element of the disease, by virtue of its astringent properties, and inclines to the belief that it acts in a parallel manner with ergot.

When general asthenia has developed, he considered it of great importance to institute general analeptic treatment, and recommends the use of remedies like strychnine, valerian and cinnamon, which are to be alternated with iron. The mineral acids, especially nitric and sulphuric, are of value in certain conditions of this disease. The general condition of the patient apart from the direct disease should not escape our most careful attention, not only by reason of his or her comfort, but for the beneficial effects which such measures exert upon the diabetes.

ACUTE MILIARY TUBERCULOSIS.

BY CHARLES R. CRANDALL, M.D.,
Of Portland, Maine.

A. M., aged 43 years, and a mechanic by trade, was tall, of dark complexion, and well built. Had always enjoyed good health up to the commencement of the illness now to be described. His family history was good, both parents and several brothers and sisters now living.

For three weeks previous to coming under observation he had suffered from frequent irregular chills and sweats, which, according to description, simulated those of malarial origin. These recurred more or less each day, but were without the phenomena of periodicity. There was also more or less fever during this period of the disease, but not sufficient to cause the patient much alarm. Associated with these more marked symptoms, were also some cough and a noticeable decline of strength, which finally made it necessary for him to give up work, and seek medical treatment. There was also impairment of appetite, but otherwise digestion was apparently good, and the bowels acted with natural regularity.

When first seen, three weeks from the commencement of the disease, and two weeks previous to death, the appearance of the patient was well calculated to attract attention. The facial expression was that of one having been on a debauch. The countenance was haggard, the eyes unsteady and wild in their expression, while the forehead was wrinkled and bore evidences of some recent superficial abrasions. The signs of debility were most striking, as shown by the haggard countenance, by general tremor of the hands, arms, legs, and muscles of the face. Another no less noticeable objective symptom was the peculiar dusky, livid hue of the skin upon the face and neck, and which was also found to be quite general over the entire surface of the body. In shade the hue was much like that peculiar to typhus fever, or to that sometimes seen in cases of typhoid pneumonia.

At times this peculiar lividity would become intensified and take the form of "come-and-go-flushes," and these in turn would fade out into ashen or cadaverous shades.

At this time the pulse was 110, temperature 102, and breathing was somewhat accelerated. Harsh or exaggerated inspiration was general throughout the chest, and expiration was prolonged. Normal resonance all over the chest, with the exception of a slight elevation of pitch at the right apex. Aside from over action, the heart was not affected. The urine was also found to be normal. The abdomen was normal in tension and there was no tenderness or gurgling in the right illiac fossa. The bowels moved once daily and the fæces appeared natural.

The patient was ordered to remain in bed and systematic observations and treatment were carried out. The above-described symptoms intensified rapidly, and there followed a marked decline of vitality, although the treatment was of a most sustaining character.

One week from the time the above symptoms were noticed, the dusky hue was increased, if anything. The pulse varied between 110 and 150, with extremely low tension. Respiration had increased to 56 per minute. The temperature was continuously elevated, ranging from 102 to 104½. Spells of profuse sweating occurred at irregular intervals during both day and night. Upon inspection could be seen the rapid and labored breathing, the generally good distention of the entire chest, but now it was evident that the right side was not quite so expansile as the left. Percussion resonance nearly normal all over the chest, excepting a slight increase of the elevated pitch at the right apex. Auscultation, at this time, detected an increase of the harsh inspiration; prolonged expiration, especially at right apex; good expansion of the air vesicles; no bronchial breathing, either anteriorly or posteriorly.

Towards the end of the second week under observation, or the fifth week of the disease, the general symptoms continued about as mentioned above; the most noticeable being the livid hue, the weak, rapid pulse, the high temperature, the rapid breathing, *subsultus tendinum* and the presence of fine mucous râles throughout the chest. Finally, exhaustion became complete, the temperature declined for several hours until it reached about normal, and death ensued, occurring at the end of the fifth week of the disease. Cough and expectoration were slight during the entire course of the disease. There was no delirium and the only brain symptom of note was a seeming dullness of mind or general indifference.

Post-mortem.—The body retained the dusky or livid hue. The venous system was everywhere engorged. The lungs were of a deep purplish shade; their surfaces were studded everywhere with miliary tubercle. To the touch, the lungs were dense, semi-elastic, and felt as if fine shot were imbedded throughout their structure. On section the connective tissue was found to be uniformly filled with "miliary nodules, which present that gray, translucent appearance of fresh tubercle." In places here and there in the inferior lobe of right lung tubercles had begun to soften and were in the first stages of caseous degeneration. There was an excessive deposit of tubercles at the right apex, which explained the high pitch causing percussion dullness before referred to. There were no cavities in the lungs. Deposits of tubercle were also found in the liver, kidneys, spleen, and intestines. The right heart was filled with black, clotted blood.

The brain was not examined.

Acute miliary tuberculosis has been defined by Bartholow to be a febrile affection due to deposit generally throughout the body of the gray tubercle granules. It is a disease remarkable for its obscurity, for its rapid progress, and also for its fatality. Moreover, it is a disease well calculated to deceive, not only on account of its rarity, but also for its tendency at the outset to simulate other diseases. In some cases the repeated chills, high temperature and night sweats are highly suggestive of malarial infection. Other cases simulate typhoid fever so completely that Trousseau speaks of a typhoid form of galloping phthisis. It is in this form that the dull expression of countenance, low delirium or headache, *subsultus tendinum* and morning and evening oscillation of temperature are well marked. Again, acute miliary tuberculosis may be confounded with typhus, as in both there is fever, debility, rapid pulse and dusky hue of the skin.

But, after all, such confusions may generally be cleared up by a careful investigation of the history of the case and an intelligent differential diagnosis. Perhaps no other disease so well illustrates the value of diagnosis by exclusion, or what Niemeyer terms "negative information," as does this rare form of tuberculosis.

The disease is remarkable in another sense, owing to the fact that it often lights up and runs its rapid course without any assignable cause. Indeed, the etiology of the disease is not well understood.

Buhl, for instance, assigns the origin to the absorption of caseous matter from antecedent lesions, as ulcers, abscesses, or serous inflammations in other organs. Bartholow adopts the view "that the gray granulation is deposited throughout the body under the influence of certain kinds of irritation; it is necessary that a peculiar vulnerability of the constitution exist; in other words, that it be of the scrofulous type."

On the other hand, Niemeyer declared, owing to cases occurring without any trace of antecedent lesion, that acute miliary tuberculosis is a secondary disease arising in some manner as yet unknown to us, from the pernicious effect of the cheesy deposit; but that may proceed from other causes of whose nature we are equally ignorant.

Concerning the case under consideration there were no evidences of antecedent lesion, primary disease, scrofulous diathesis, or hereditary tendency.

The symptoms of acute miliary tuberculosis are well worthy of further remark. In cases occurring independent of primary disease, the most important early symptoms are rapid decline

of strength, more or less chills, rapid breathing, dyspnœa and fever. The chills come on rather abruptly and are more or less persistent. They may be suggestive of malarial chills, but, if anything, they are more like rigors, being without periodicity. There is also more or less continuous fever with remissions, hence the temperature may range from 100 to 104½. The temperature is of especial value in diagnosis, for it is calculated to excite the closest scrutiny, and should suggest the presence of a grave constitutional disease. The temperature is not at all influenced by remedies, but continues moderately high and changeable until the last week of the disease, when it gradually declines, falling to about normal just before death. Early in the course of the disease sweats are generally a noticeable symptom; they usually occur during the remission of the fever. They are of en very profuse and persist with varying frequency during the entire disease. To some, the sweating and the condition of the skin are remindful of the death agony (Bruen). Respiration becomes accelerated in the early stages, and is one of the most marked and characteristic symptoms. The frequency ranges from 30 to 60 per minute, and, as a rule, is thus maintained until death.

Cough is also a usual attractive symptom, which is due, probably, to irritation of nerve filaments by tubercular deposit. Later on cough may result from the effort to expectorate catarrhal mucus, the presence of which is due to hyperæmia of the bronchial tubes. Cough, however, is a variable symptom, said to be marked in some cases and nearly absent in others.

An extremely rapid pulse is also one of the marked features, and one which is sustained from first to last. The frequency varies from 110 to 150, and is often out of proportion to the temperature. The pulse is small, weak, often becoming thready, and is strikingly suggestive of the great exhaustion that is going on. By some authorities this persistently rapid pulse is given great diagnostic prominence, and is esteemed a fundamental symptom of this malady (Bruen).

In this form of tuberculosis there are generally well marked nervous symptoms, but they are not characteristic. If present, they are much like those of typhoid fever, and hence, there may be stupor, headache, possibly low delirium and *subsultus tendinum*. In the cases now under review, the nervous symptoms were prominent, as shown by fibrillary movements all over the body, and general unsteadiness and tremor of the limbs.

The dusky hue or lividity of the skin, before alluded to, is another important and common symptom. It may appear quite early, but generally is most marked in the latter stages of the disease, when circulation has become very feeble and the excessive deposits of tubercles have impinged upon the arterioles, preventing due aeration of the blood.

Singularly enough, physical examination is often unsatisfactory in the highest degree, save as a method of obtaining "negative information." Indeed, it is positively confusing to come across a patient having dyspnœa, rapid breathing, probably cough and expectoration, a cyanosed skin, and then not be able to find any physical signs of pulmonary disease. Yet such may be the case in the earlier stages of acute miliary tuberculosis. As a rule, inspection will not discover any change in the contour of the chest. Auscultation may, in all probability, discover harsh inspiration, feeble expansion and prolonged expiration. The presence of fine mucous râles in the bronchi may also possibly be detected. In some cases, however, none of these signs will be discovered by auscultation. Toward the end of the disease the râles referred to are generally present in considerable numbers. Percussion, as a general thing, is as unsatisfactory as inspection and auscultation. If the percussion note is changed at all, it is when the disease is well advanced, and is manifested by a slight elevation of pitch at the apex of one or both lungs. The question may well be discussed, since there is such an abundant deposit of tubercles, why is there not more dullness on percussion? It is because the tubercles are very generally distributed "in the sheaths of the arterioles, the sheaths of the bronchial filaments, and in the lymphatic vessels." Therefore, the alveoli and bronchi maintain, to a large degree, their distended and expansile condition. Hence, resonance is afforded on percussion. On the other hand, in chronic tuberculosis the tubercular deposit is generally localized, and is followed in time by inflammatory changes, caseous degeneration and extensive infiltration, all of which causes solidification of the parenchyma. Hence, it is common to find circumscribed areas of dullness in chronic tuberculosis.

In regard to physical examination in acute miliary tuberculosis, Niemeyer declared that the most persistent examination of the chest reveals nowhere that the substance of the lung is infiltrated. And upon the same subject, Ruehle said that in particular, there is seldom noticed any abnormity in the percussion note; at most, only some impairment of the tone at various parts of

the chest, as compared with the corresponding situation on the other side, or a slight tympanitic quality, changes which are not constant, but alternate on repeated examinations. Moreover, the same author goes on to say that there is no single symptom nor group of symptoms sufficiently distinctive to make the existence of acute miliary tuberculosis a necessary inference during life. The certainty of the diagnosis can only be approximative.

The latter statement, however, will not apply in every instance. The disease presents an ensemble of symptoms which, by one who has studied and carefully watched one or more cases, will hardly be mistaken. The writer remembers with pleasure, how rapidly and certainly his distinguished teacher of physical diagnosis, Dr. Bruen, of the University of Pennsylvania, diagnosed the case in hand. The diagnosis was in no sense approximative, but was positive, and from the first was verified at the post-mortem.

During the earlier stages of acute tuberculosis the diseases most likely to be suggested to the mind by the appearance of the patient are intermittent fever, catharrhal pneumonia and typhoid fever. It is believed, however, that an observation of the following differential points will tend to aid in establishing a correct diagnosis :—

Acute Miliary Tuberculosis.	*Intermittent Fever.*
1. Chills occur at irregular periods.	1. Chills occur periodically.
2. Fever remittent in character, and not influenced by treatment.	2. Fever intermits and yields to treatment.
3. Pulse rapid and weak, with tendency to increase.	3. Pulse rapid and full during fever, and then subsides.
4. Temperature constantly elevated, with variations between 100 and 103.	4. Temperature characterized by extreme changes.
5. Marked disturbances of respiration.	5. No disturbance of respiration, as a rule.
Acute Miliary Tuberculosis.	*Pneumonitis.*
1. Onset gradual.	1. Onset rapid.
2. Chills frequent and more or less persistent.	2. Usually one severe chill followed by more or less chilly sensations.
3. Temperature runs up gradually, never extremely high, subject to remissions.	3. Temperature rises very rapidly to about 104, continues high for a few days and then begins to decline.
4. Irregular sweats are a common symptom.	4 Sweating is more or less frequent, and continuous in some cases.
5. Pulse rapid and weak from the first.	5. Pulse rapid but full and strong during first stages
6. Cyanosis and lividity a prominent symptom, but most marked during the later stages.	6. Cyanosis or flushing a common symptom early in the disease.
7. Rapid breathing a marked symptom.	7. Rapid and shallow breathing a marked symptom.
8. No soreness or pain in the lung.	8. Usually more or less pain
9. As a rule, no dullness on percussion.	9. Dullness sooner or later over a portion of one or both lungs.
10. Crepitant or coarse bronchial râles may or may not be present at first, but frequently appear during the later stages of the disease.	10. Crepitant and sub-crepitant râles; mucous and submucous râles in the larger tubes, appearing within the first 24 or 48 hours.
11. More or less cough and expectoration generally present.	11. Cough a marked symptom. Expectoration becomes abundant, sputa often discolored.
Acute Miliary Tuberculosis.	*Typhoid Fever.*
1. Onset gradual.	1. Onset gradual.
2. Frequent chills.	2. Usually a chill followed by chilly sensations.
3. Possibly more or less headache.	3. Headache generally complained of.
4. Mental disturbance and delirium not the rule, but may occur.	4. Mental disturbance and delirium a common symptom.
5. No epistaxis.	5. Epistaxis a common symptom.
6. Tongue usually dry and coated.	6. Tongue dry and coated.
7. Bowels may or may not be normal.	7. Bowels generally loose. Exceptionally, constipation may exist.
8. No abdominal tenderness or tympany.	8. Abdominal tenderness and tympany.
9. Temperature rises gradually, and there may be evening exacerbations and morning declines.	9. Temperature rises gradually, and generally has a regular evening exacerbation and morning decline.
10. Râles are generally present sooner or later.	10. Râles are frequently present, sooner or later.
11. Breathing soon becomes rapid and so continues.	11. Breathing but slightly if any changed, unless complication supervenes.
12. Pulse rapid and weak.	12. Pulse rapid and weak.
13. Generally either marked cyanosis or lividity is a common symptom.	13. Cyanosis not often present.
14. More or less profuse sweats a common symptom.	14. More or less sweating in about half the cases; in the other half the skin is hot and dry.
15. No eruption.	15. Eruption may appear after seventh day.
16. Subsultus tendinum may exist.	16. Subsultus tendinum may exist.

Of course, the above distinctions are merely approximative, and therefore will be more markedly defined in some cases than they will be in others. As is generally admitted, one of the peculiarities of the disease in question is its similarity to several others, and hence there is a wide range of variability in symptoms. Indeed, Bartholow, in summarizing the great similarity between some cases of acute miliary tuberculosis and typhoid fever, says as follows: "The cases, as a rule, present a striking analogy to typhoid, not only in the symptoms as described but in the physiognomy of the patient, the decubitus, the utter prostration, and in the course of the disease."

The basis of the diagnosis of acute miliary tuberculosis must rest on the marked evidences of some serious intra-thoracic disease, as shown by the rapid breathing, the cough and expectoration, and the general bad condition of the patient. On the other hand, the diseases to which it presents a striking analogy must be excluded by "negative information."

The prognosis of the disease is death. The duration, on an average, is about five weeks. The

patient perishes from the destructive fever process and the tubercular obstruction which prevents the due oxygenation of the blood. Perhaps no better idea of the rapidity of the disease and the appearance of the patient could be obtained than is conveyed by a recorded description of a case by that matchless clinician, Trousseau.

"On the 2d of February 1861, my colleague, Dr. Barth, and I were sent for to Les Ooiséaux Convent, to see a young Spanish lady, sixteen years of age. Her ordinary medical attendant, Dr. Vosseur, informed us that this young lady had, a fortnight previously, begun to have uncomfortable feelings and to suffer from fever, without experiencing any local symptoms, excepting decided oppression in breathing. As the symptoms continued, Dr. Barth was sent for, eight days later; at that visit he was struck with the lividity of the lips and face; the lividity extended to both hands. There was great oppression of breathing and ardent fever. Nothing abnormal could be detected by the most careful auscultation; there was neither râle nor the sound of prolonged expiration. The functions of the stomach were as well performed as it were possible to desire. Eight days after that visit of Dr. Barth, I again met him in consultation on the case. There was then extreme frequency of pulse and respiration and a frightful increase in the lividity of the skin. During the night the patient had had insomnia and some raving. Throughout the whole extent of the left lung we heard very fine subcrepitant râles, mingled with mucous râles; there was no expectoration. She died on the 4h of February, seventeen or eighteen days from the beginning of the attack."

Periscope.

Bald Tinea Tonsurans.

Dr. Liveing writes to the *British Medical Journal* as follows:—

On several occasions I have called attention to the occurrence of smooth, bald patches in tinea tonsurans, exactly resembling alopecia areata. I have also mentioned the fact that when, in these cases, one patch becomes quite bald, the others quickly follow suit. A remarkable example of this has lately come under my observation. Two brothers have been under my care for some time past, with ordinary well marked tinea tonsurans, with abundance of the trichophyton. Their parents objected to vigorous treatment, and therefore mild remedies only have been used, which have not at any time produced the slightest soreness. The elder boy had six or seven separate spots of tinea tonsurans, and, during the last fortnight, every one of these spots, great and small, have become perfectly bald, smooth, and shining, with a well defined margin of healthy hair. What I wish especially to call attention to is (1) the suddenness of the change, (2) that the bald spots are strictly confined to patches previously affected with tinea tonsurans, not a trace of baldness existing on any other part of the head. In this instance there is not a stump nor a hair to be found, though, when I previously saw him, the patches were thickly covered with stumps and hairs. In other cases of this kind that I have met with, it has been generally possible to find one or two stumps left, either on or at the margin of the patch, by the microscopic examination of which the nature of the case could be determined. When the baldness is as perfect as it is in this instance, we may probably regard it as a spontaneous cure. In the younger boy the tinea tonsurans has run an ordinary course. It is somewhat difficult to say whether we should regard a case of this kind as one of true alopecia areata following on tinea tonsurans, or as a peculiar and exceptional feature in tinea tonsurans itself. Nor do I think the question of much importance, provided we remember that infection is not always removed; or, in other words, that the denudation is not in every case so complete as to remove all the stumps affected with the *Trichophyton tonsurans*. A want of knowledge of this fact has, in past times, led to two mistakes; the one, that alopecia areata is a *parasitic* disease; and the other, that it is *occasionally contagious*.

It has been pointed out by several observers that in almost all chronic scaly affections of the skin one can, by a diligent examination of the scales under the microscope, find the spores of a vegetable parasite, commonly called *Torula vulgaris*. I can confirm this from my own observations. This parasite is quite harmless, and is rather a consequence than a cause of the disease.

Red Sweat.

The *Lancet* says: It has long been suspected that the red as well as the blue color occasionally observed in perspiration is due to the presence of bacteria. In a woman whose sweat, especially in the axillæ, had a red tinge, Hofmnan, in

1873, found that uniform red masses adhered to the hairs, but he did not ascertain their nature. Pick observed in a peculiar case of skin disease reddish masses of bacteria on the hairs. Eberth noticed bacteria in yellow sweat. Additional observations of the same kind have been reported by Babesiu, of Pesth. A woman twenty six years of age presented pale red sweat in the right axilla, where the skin and hair were also slightly reddened. From time to time the perspiration became blood-red in color, associated with hysterical and nervous disturbances. A sister who slept with her also became affected in similar manner, the perspiration in the right axilla becoming red. A third case presented itself in a young healthy man, who complained of occasional blood-red sweat; and a fourth in a young woman. In all the symptom was associated with troublesome itching. Microscopical investigation yielded in all the cases a similar result. The hairs of the axilla were thin, pale-red, brittle, and surrounded with a colloid-looking, rusty or bright red sheath, in places of considerable thickness, and having a rough surface. It consisted of red masses presenting a radiating striation, more or less confluent, apparently proceeding from fibres of the cortex of the hair or from some broken part of its surface. The radiating striation was found to be due to the aggregation of round or ovoid bacteria, scarcely a micro-millimeter in diameter, which were united in zooglœa masses by a reddish intermediate substance. Nodular swellings on he hair were produced by an infiltration of the organism between the separated fibrils. The roots of the hair were free from bacteria. The red tint of the sweat was found to depend upon numerous roundish masses of zooglœa, resembling those of Bacterium prodigiosum. The bacteria were deeply colored by anilin and hæmatoxylin, and were rendered more distinct on the addition of acetic acid or liquor potassii, while the zooglœa shrank under the influence of alcohol, ether, and turpentine. Sulphuric acid changed the red color to violet, and then to violet blue. In sterilized culture solutions the bacteria multiplied slowly. The conclusions drawn from these observations are that the red sweat often found in the axilla is colored by a sphero-bacterium, the development of which gives rise to an excessive perspiration, and sometimes to brittleness of the hair, itching, and slight tinting of the skin. The red sweat appears to be contagious. The bacteria resemble, on the one hand, the colorless zooglœa found in hair, and, on the other, certain chromogenous bacteria, especially B. prodigiosum, from which it is distinguished by the brick-red color of the intermediate substance. It is more difficult to cultivate than B. prodigiosum, but gives essentially the same chemical reactions.

—M. Schlagdenhauffen, of Nancy, has studied the seed of an African plant known by the name of la pola. Its cotyledons contain caffeine and tannin. The Arabs use it to improve impure water. M. Schlagdenhauffen, in a note from him read at a meeting of the Académie des Sciences, stated that he considers la pola may rank in utility with tea and coffee.

Reviews and Book Notices

NOTES ON CURRENT MEDICAL LITERATURE.

——Address in Hygiene. By Benjamin Lee, M.D., PH.D., Philadelphia. Extracted from the Transactions of the Medical Society of the State of Pennsylvania for 1881.

——Review of the Drug Trade of New York for the year 1881. Prepared by D. C. Robbins Esq., for the twenty-fourth annual report of the Chamber of Commerce of New York State.

——An analysis of seven hundred and fifteen consecutive cases of skin disease, by H. W. Stelwagon, M.D., comes to us in the form of a reprint. This is a very interesting article for dermatologists.

——A case of Basedow's Disease, terminating in total loss of sight from (neuro-paralytic) inflammation of the cornea, by Henry G. Cornwell, M.D., of Columbus, Ohio, comes to us as a reprint from the *American Journal of the Medical Sciences*, October, 1880.

——Intermittent Spinal Paralysis, of Malarial Origin. By V. P. Gibney, A.M., M D. Reprinted from the *American Journal of Neurology and Psychiatry*. The author concludes "that there may be spinal paralysis affecting one side or a single member, clearly traceable to malarial poisoning. They are not numerous, however. If nervous diseases are increasing, as many authorities claim, may we not expect to find the cerebro-spinal axis the more readily and the more frequently influenced by malarial poisoning, just as we find now the nerves so commonly affected?"

BOOK NOTICES.

Lectures on Diseases of Children. A Handbook for Physicians and Students. By Dr. Edward Henoch, Director of the Clinic and Polyclinic for Diseases of Children, in the Royal Charité, and Professor in the University of Berlin. pp. 357. New York: William Wood & Company, 1882.

This volume constitutes the March number of the well known "Wood's Library of Standard Medical Authors." This treatise is based upon a most extensive experience of thirty-seven years. Throughout the work the author makes frequent reference to a list of prescriptions at the end. This is done principally to aid young physicians just commencing to practice among children. Unfortunately these prescriptions are written in the metric system, which is comparatively unfamiliar to the mass of the profession in this country. It is otherwise a good book, and to be highly recommended.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

SUBPŒNAS TO MEDICAL MEN.

This is a subject for the consideration both of the jurist and the physician. A subpœna to any one must always be obeyed, and its disregard, considered contempt of court, is usually severely punished. In the majority of cases this is eminently just and commendable. The merchant, the lawyer, the gentleman of fashion and the *loafer* can obey a subpœna without any detriment to his own welfare or to that of any one else. The case, however, is oftentimes far different with the physician. Suppose he has been subpœnaed to appear in court on a certain day at ten o'clock. He may be called at seven or eight o'clock of the same day to a case of labor, and when half-past nine o'clock comes his patient may be suffering from post-partum hemorrhage, when to leave her would be to insure her death. Of course, we doubt not that, in such an extreme case, the court would deal leniently with the delinquent, but such would depend very much on the character of the particular judge, and since these men are only human, we can readily conceive that even under such pressing circumstances and with such ample excuse, there would be found judges ready to inflict the severest penalty on the physician. Such ought not to be the case, for two reasons.

1st. It would be unjust to punish a man for neglecting a lesser to perform a greater duty.

2d. It is a temptation for some men to neglect a duty, for the neglect of which they *may* not be held responsible, to fulfill one, for the neglect of which the punishment stares them in the face.

It would be well to have this matter clearly understood. Physicians are, by law, on account of the pressing necessities of their professional duties, exempted from jury duty; so ought they likewise to be exempted from subpœnas, when it can be shown that attendance in court as a witness will redound to their own and their patients' disadvantage. Witnesses are often compelled to remain idly in court for hours. Physicians in active practice cannot afford to waste this time. Of course, there are certain criminal cases in which the evidence of the physician is absolutely essential, but in such trials his convenience ought to be consulted, and he ought to be most liberally rewarded. In civil suits he ought not to be forced to neglect his patients. These few words are intended to direct thought and to turn legislative energy in this direction.

INSANITY FROM DRUGS.

We take pleasure in calling attention to a circular from Dr. H. H. Kane, which appears in another column. His object is a most worthy one. No doubt many cases of insanity are directly traceable to the abuse of strong and powerful drugs, and it will be of great interest to the profession to have reliable statistics on this subject. We would, therefore, earnestly commend this circular to all physicians, and strongly urge them to answer the questions contained therein to the best of their ability. By so doing they will advance science; and to advance medical science ought and *must* be not only the duty, but the pleasure of every true physician. Therefore, we would urge all our readers to be prompt in answering this circular.

News and Miscellany.

Medical Society of the State of Pennsylvania.

THIRTY-THIRD ANNUAL SESSION.

Pursuant to adjournment, the Society met in Battery Armory, Titusville, Pa., May 10th, at 10 A.M., and was called to order by the President, Dr. Jacob L. Ziegler.

Prayer was offered by the Rev. Dr. Henry Purdon, after which the list of delegates was read by Dr. Wm. B. Atkinson. Dr. Geo. O. Moody, of Titusville, then delivered the

Address of Welcome.

Mr. President and Gentlemen of the Pennsylvania State Medical Society :—

It will ever be a pleasant reminiscence that the honor of greeting you on this your first meeting in Crawford County has been assigned to me. As the representative of the Crawford County Medical Society, I am to welcome you as an organized body of workers in the broad field of theoretical and practical medicine. As the representative of the citizens of Titusville, Pa., I am to welcome you individually, trusting that your brief visit among us will not be entirely destitute of social enjoyment, and confident that our own anticipation of pleasure and profit will be fully realized.

We can present to you, gentlemen, for your admiration, no ancient historical records of our city, whose history has not been written—we trust not yet lived. We can point you to no enchanting natural scenery to delight the eye, no fine architectural designs nor rare gems of art, to please the æsthetical taste. Were you here only in pursuit of recreation and pleasure, these would be fatal defects. We are told that travelers in foreign lands are wont to go into ecstacy at the sight of ancient ruins. If modern ruins will answer your purpose you shall have a free show, and can feast the eye to the heart's content. But neither our modern ruins nor our want of natural scenery and institutions of public interest will deter us from giving the most profound attention to your words of wisdom, feeling, as we do, that the chief object of your meeting here is to reëxamine the past history and present condition of medicine, to place on record whatever has been proven and found valuable, and to reject whatever has failed to stand the crucial test of scientific research and practical experience. You are also to reach out into the unexplored regions of physiology, pathology, surgery, therapeutics, and all the branches, direct or collateral, of our profession, to gather in new facts and develop new theories, in their turn to be proven true or false by future investigations.

Our profession has a right to demand of all such organizations as this, that at every meeting it shall add something to its fund of scientific and practical knowledge, should help to mark the boundaries of its established truths and elevate it to the dignity of a fixed science.

But we are not medical men *only*, nor is the debt we owe due *alone* to our profession. That power from which our Society has derived its corporate privileges has a right to our allegiance and to demand from us, for the public good, a knowledge of those sanitary laws necessary to protect the public health and add to the sum of human life. So also does that Higher Law—the source of all human law—make it incumbent upon us, not only to heal the diseases and relieve the sufferings of our fellow creatures, but to warn the masses throughout the State, and especially those in whose midst the Society meets from year to year, where they are to look for and how contend against those unseen pestiferous poisons, which, like the breath of the deadly upas, silently creep into the homes and bedchambers of their unconscious victims, filling our land with the lamentations of Rachels, and entailing upon thousands a life of disease and misery. The education of the people in hygienic and sanitary laws becomes more and more imperative, as, year by year, preventive medicine advances to the front, and becomes the pioneer of the curative art. If we are not our brothers' keepers, the day is not far distant when an enlightened public opinion will demand of us, as the conservators of the public health, that we so instruct our brothers and fellow-citizens as to enable them to be their own keepers and the keepers of those whom nature's law has placed under their protection. Confident, from the past history of our Society, that it will not neglect its duties to the medical profession, I sincerely trust a voice will go out from this meeting upon the importance of the proper construction, ventilation, heating, and sewerage of our homes, so strong and so clear, that it will be heard and heeded by every inhabitant of our country. Again, gentlemen, allow me to bid you a hearty welcome, and a God speed in the work before you.

The committee of arrangements then presented their report, after which followed the introduction of delegates from other Societies and of visitors not delegates.

Report of Delegates to other Societies.

Dr. Laurence Turnbull, of Philadelphia, presented a written report of his visit as a delegate to the Centennial Meeting of the Massachusetts Medical Society, at Boston, June 7th, 1881.

The meeting was one of great interest, and Dr. Turnbull alluded to the valuable historical address of Dr. Samuel A. Green, now the efficient mayor of that city. He also gave an abstract of the address of President Eliot, of Harvard University ; and the able reply of Dr. Williams, the distinguished ophthalmologist, President of the Massachusetts Medical Society, in which he returned thanks for the graceful hospitality extended to them. He also stated that it was owing to the fostering care and willing coöperation of the college with the Society that the standard of education in the medical school has been kept so high. One of the most instructive features of the celebration was the exhibition of instruments, apparatus, books and medicines, dating from the fifteenth century up to the present day. But the crowning event was the centennial anniversary exercises, which included addresses and a splendid poem by the renowned Oliver Wendell Holmes.

After which the ordinary routine business as per programme was transacted. (See Reporter, April 15th.)

MAY 10th, 2. P. M.

After the transaction of the routine business, the address in Surgery was delivered by Dr. H. L. Orth, of Harrisburg. A paper on Gheel was read by Dr. S. S. Schultz, of Danville. Following this came a paper on

The Oleates and Oleo-Palmitates in Skin Diseases,

read by John V. Shoemaker, A.M., M.D., of Philadelphia, Physician in charge to the American Hospital for Skin Diseases, etc.

At the meeting of the Society, in 1879, Dr. Shoemaker called attention to the oleates for dermic medication, and spoke at length upon the great value that they possessed over the *ordinary* ointments then in general use.

Dr. Lawrence Wolff, of Philadelphia, has found the best and most ready method for preparing oleates by the double decomposition of sodium oleate with solutions of neutral salts, and as a general method of their manufacture, proposes the preparation of the former by a saponification of oleic acid with a solution of sodium hydrate. A solution thereof, in eight parts of water, is precipitated by the salt required; the precipitate, washed and dried, thus yields the oleate required. Of the manner of preparing each individual one, he shall speak under their respective headings.

The oleates of mercury, atropia, quinia and antimony, with their therapeutical action, were considered, and Dr. Shoemaker claimed to have first introduced the oleates of lead and bismuth, in 1879, before the Society. The author also brought forward and showed for the first time the following oleates:—

OLEATE OF ZINC.

Oleate of zinc is made by decomposing a sodium oleate, with a saturated solution of zinc sulphate, boiling out and drying the precipitate and then reducing it to an impalpable powder, which is rapidly accomplished. One part thereof melted with three parts of a fatty vehicle, yields the ointment he has been in the habit of using. He has, however, obtained the very best results with the oleate of zinc alone, and not mixed with a fatty diluent; which is a fine pearl-colored powder, with a soft-soapy feel, very much like powdered French chalk.

When dusted over a denuded surface, it will have, by the combination of the oleic acid and zinc, a stimulating as well as astringent action. It is, *par excellence*, the remedy for excessive sweating, or in cases of hyperidrosis and osmidrosis. I have used it for more than a year, dusted over the surface, in patients suffering from an increased flow of sweat about the palmar and plantar surfaces, and around the axilla and genitalia. It has relieved and permanently cured some of the most distressing cases suffering with excessive secretion about the feet, in which the epidermis had macerated and peeled away, leaving a tender and exposed skin, and giving rise to a very disagreeable odor. It is likewise most efficacious as a lady's toilet powder, particularly to those who are afflicted with shining faces in the summer, called seborrhœa oleosa. It is the most valuable and the most reliable remedy in that commonest variety of eczema known as eczema vesiculosum. He has witnessed, and also those who have been in attendance in his clinics during the past winter, marvelous results from dusting this oleate over those on whom the extremities and even the trunk had been covered with small vesicles, swollen, hot, inflamed, the parts constantly weeping, and the itching so intense that the patient would rub and scratch the surface until it had become perfectly raw; in such cases he has frequently seen the discharge dry up, the swollen and inflamed skin resume its normal condition, by the threefold action of the oleate in protecting, stimulating and astringing the parts. If this oleate be dusted on an inflamed surface that is hot and tumid, such as is found in erythema about the groins and axillæ, and in herpes, particularly of the genitals, it will cling to the skin, and will not fall or brush off like ordinary dusting powders. These advantages prove, beyond a doubt, the superiority of the oleate of zinc over the ordinary ointments and powders in the class of skin eruptions he has just named.

OLEATE OF COPPER.

Copper oleate is obtained in a similar manner, by double decomposition with a saturated solution of copper sulphate. The washed precipitate melted with either four or nine parts of cosmoline, fat, or lard, gives respectively a twenty or ten per cent. of oleate of copper ointment.

When applied to the unbroken skin, the oleate of copper ointment rapidly penetrates deeply into the parts, particularly into the follicles, and will produce slight stimulation. On the other hand, if brought into contact with broken skin which it stimulates, an insoluble albuminate is formed, which coats over the surface and supplies the place of the abraded skin.

The most successful results that he has had with the ointment of the oleate of copper has been in rapidly curing cases of ringworm. He directs it to be used in the following manner, both in ringworm of the scalp or body: The parts should be first washed with soap and water, and in case the hairs be involved, the hair should be cut short, and after drying, a small piece of the ointment of this oleate, in proportion to the size of the patch, should be lightly rubbed on the surface. The same procedure should be repeated night and morning, until all trace of the disease had disappeared; the parts should only be washed about once in ten or twelve days, as the too frequent use of water may prevent the oleate from penetrating to the lowest depths of the follicle in order to successfully destroy the fungus. It may also be necessary to pluck out the diseased hairs, or epilate, in very inveterate cases, although he has cured some without being compelled to get rid of the diseased hairs in this manner. If this method is carefully followed, the oleate just named will no doubt effect a complete cure in some of the most obstinate cases. He has also used this ointment, spread on old muslin, for indolent ulcerating surfaces; and has found it an excellent cleanser and healer. It acts by condensing the tissues, and constringing the blood vessels, and thus lessens the determination of blood to the part. It will relieve, and some of his patients have reported cures from its application to, hard and horny warts, corns and bunions.

OLEATE OF ALUMINIUM.

Aluminium oleate is also prepared by decomposing sodium oleate with aluminium sulphate; the washed precipitate mixed with equal parts of lard gives the ointment of aluminium oleate he shall speak of.

The ointment thus prepared is semi-solid, dark brown in color, and having a most powerful astringent action. It has the most decided action of all the other oleates in checking muco-purulent discharges that occur in one of the varieties of eczema. For this purpose it can be applied with advantage around the arms, groin or buttock of those who have excessive discharge from the friction of those parts—particularly in children and infants—and so check the profuse secretion or bring the parts into a suitable state for other remedies. It can also be employed with success as a dressing in foul ulcers, abscesses, sinuses, burns, and scalds, from its power to coagulate albumen, constringe the vessels, by its anti-styptic action, and check or correct the secretion of muco pus.

OLEATE OF IRON.

Iron oleate: precipitate with ferrous sulphate from sodium oleate on boiling is soon converted into ferric oleate; and as such may either be used pure, or if mixed with an equal amount of a fatty base, as his ointment of iron oleate.

When prepared in the above manner, it occurs in a reddish-brown paste, inodorous, having a styptic taste, and readily soluble in fats, which hold in combination about 30 per cent. of the oxide of iron; forming a powerful and important therapeutic remedy. It is free from local irritation when used topically, but when brought in contact with an ulcerating surface it has a very mild astringent action. It can, therefore, be used, as he has tested it, both for a constitutional and local effect. He has already had some excellent constitutional (systemic) results, having a small piece of this ointment rubbed in the axillæ and inguinal regions, two or three times a day. The effect of this ointment has been very good on some upon whom he has applied it, who had a deranged state of the digestive organs, and inability to bear the ordinary chalybeates, weak pulse, and a pale and flabby condition of the skin. He has also been using it with marked effect in some cases of scrofula. He is now testing its therapeutic action, not only in cutaneous affections but also in many other diseases, from which he expects shortly to hear favorable and satisfactory results. It will no doubt take the place of other chalybeates—particularly when the latter are not well borne by the digestive organs—and will probably constitute one of the best constitutional tonic and local astringent remedies.

OLEATE OF ARSENIC.

Arsenicum oleate must be derived by making arsenious chloride by the cautious saturation of hydrochloric acid with arsenicum metal. The solution thus obtained, precipitate from sodium oleate the oleate required, which he employs in the quantity of twenty grains to one ounce of fatty base, as his ointment of arsenicum oleate. It is in this form a soft, yellowish ointment, having no action on the skin, except when abraded or in wounds, ulcerating and granulating surfaces, in which condition it will excite active inflammation and destroy the tissues of the part to some depth. In lupus, especially the ulcerating varieties, the constant application of the ointment of arsenicum oleate will destroy cell infiltration in a mild, and in a comparatively painless manner. It may be applied with almost as good result in the tubercular form of lupus, providing the parts be thoroughly scraped, so as to bring the oleate in contact with an abraded surface, which will greatly enhance its action. It can be used very satisfactorily in the ulcerating variety of epithelioma, and will be better borne for a longer period to the parts than any other form of arsenic. He has likewise employed it after puncturing or scraping the surface to destroy warts, condylomata, nævi, corns, horns and old granulations. In some instances he has incorporated in this oleate, with a very happy effect, opium, belladonna, hyoscyamus and arnica.

OLEATE OF SILVER.

This new oleate, like the others, is prepared by precipitating the sodium oleate with a saturated solution of silver nitrate, washing the precipitate with boiling water, and drying it, after which it is reduced, like the zinc oleate, to a fine powder. One drachm of this dissolved in an ounce of fatty vehicle forms what he has employed as ointment of silver oleate. Made in this manner, it occurs as a pulverulent salt, of brownish-yellow color, which, if mixed with lard in the proportion of from ten to sixty grains of the oleate of silver to one ounce of lard, forms a dark brown, soft and pliable ointment.

This oleate in its natural form, sprinkled over old chronic ulcers, bed sores, and exuberant granulations, will set up a healthy state in the parts. The best effects he has experienced from using the ointment of this oleate, which not only coats over an abraded surface by combining with the albumen, and so protecting it from the air, but it also causes powerful contraction of the blood vessels, and thus condenses the tissues. It is a safe and efficacious remedy in erysipelas, and can be used either around the margins, to prevent the inflammation from extending, or can be applied weak, ten to twenty grains to one ounce of lard, over the inflamed surface. It has reduced the active inflammation by being constantly applied in several cases of superficial varieties of lupus. It will be serviceable applied to boils, and carbuncles, and may often arrest pustulation in its early stage. An intolerable itching that sometimes occurs in the meatus auditorius, the anus, and the genitalia, may often be quickly relieved by applying the ointment either alone or combined with opium and belladonna. The advantages that the ointment of oleate of silver possesses over the ordinary silver ointments, are its stability and prompt action, and by being less painful and milder in its curative manner, but still penetrating deeper into the affected part.

The oleates of magnesium, lithium, calcium, antimony, tin and others, are also readily made by similar processes, but are at present of little therapeutic value as far as dermic medication is concerned, and are mentioned only for the benefit they may ultimately prove for internal exhibition.

While his experiments with these new prepara-

tions cover a period of almost two years, their efficacy and application in the treatment of dermic affections he does not claim yet as having exhausted; and while daily he finds new and valuable use for them, he will not speak of them further at this time, when they are still in their experimental stage, and would court the trial of them by other practitioners, and communications from them as to their results.

He has thus, in a brief and practical manner, endeavored to describe for the first time the therapeutic action of chemically true oleates; although he brought forward some of the same preparations before the Society in 1879.

A few years prior to that period, Mr. John Marshall, of England, published a paper on the treatment of persistent inflammations by the local applications of solutions of oxide of mercury and morphia in oleic acid. It will be observed, however, that these preparations, too, were only solutions, and not the true oleated compounds that he has just considered. While, therefore, the credit is due to Mr. Marshall for suggesting the oleic solutions referred to, Dr. Shoemaker claims to have first used the true chemical oleates, and to have used and published an account of the oleates of lead and bismuth (*See Transactions of State Medical Society of Penn'a. for* 1879), long before a description of these oleates were published and claimed by some of the foreign journals for Drs. Crocker and McCall Anderson.

The oleates in the form in which he has shown enjoy the widest range of therapeutic application. The superior advantages which they possess over the ordinary ointments, he considered under the following five heads:—

First. Their deep penetration. Second. Their freedom from rancidity. Thirdly. Their cleanliness of application. Fourthly. Their great economy, and Fifthly. Their antiseptic action.

Firstly. Their deep penetration. The oleic acid in their combination gives them active solvent powers and facility and ability to penetrate rapidly into the animal tissue, while rendering any chemical ingredient with which it is combined more active and effective in dermic medication.

Secondly. Their freedom from rancidity. The same acid held in the combination will always keep the fat—with which the oleate is mixed—pure, sweet, and free from rancidity.

Thirdly. Their cleanliness of application. The rapid absorption of the oleate into the tissue will prevent any unpleasant disfigurement of the parts, will not stain the linen, and will give comfort and ease in their application.

Fourthly. Their great economy. The oleate should not be rubbed in vigorously, like the ordinary mechanical ointments, which require considerable friction; they only require to be lightly smeared or applied over the surface in very small quantities, hence their great economy.

Fifthly. Their antiseptic action. The oleic acid in combination has also a most happy and effective action in rendering the oleates antiseptic or deodorant upon all discharges and suppurating surfaces.

A great drawback, however, to the general adoption of the oleates, will be the lack of knowledge that the majority of pharmaceutical chemists have, at the present time, of their manufacture. Thus the Doctor will often prescribe a certain oleate, and be surprised to see no change in his patient, but after careful investigation, which he has made in several instances by having the patient bring him the oleate, he has found either a substitute or an oleic solution in place of the remedy ordered. Again, it has been his misfortune to have some pharmaceutical chemists decry the action of the oleate to his patient, and from these persons he has learned that they knew nothing whatever about their manufacture. An ordinary mechanical ointment, full of lumps, was easier mixed, in the old stereotyped manner, or a spatula full of a petroleum product incorporated with some metal, was their ideal of a proper kind of a salve that should be used and would be efficacious. You will, nevertheless, find good, honest and straightforward chemists, who, if they do not understand the manufacture of the oleates will procure them for you; or will go to work and make them; but always examine their products and see that they possess all the physical properties which he showed in the excellent specimens of true and staple oleates.

This was followed by a paper on "Medicine, and Something More," by Dr. Traill Green, of Easton.

Dr. E. E. Montgomery, of Philadelphia, then read a paper on

Procidentia

and its relief, in which, after reviewing the opinion of authorities upon the true uterine support, he assumed that the vagina was the support in the normal condition, and the ligaments nature's reserve forces.

Prolapse occurs as a result of three conditions: 1st, pressure from above; 2d, increased weight of uterus; and 3d, want of support below. The most potent agents in its production are, engorgement of the uterus, frequent labor, laborious exercise, early resumption of domestic duties, neglect of laceration of perineum, and the frequent use of a widely expanding bivalve speculum.

There are three stages: 1st, simple descent; 2d, incomplete prolapse; and 3d, complete prolapse or procidentia.

The earlier symptoms are, pain in back and limbs; bearing down, burning pain in pelvis and groins, and sensation of pressure upon fundament, followed later by vesical and rectal distress and tumor at the vulva.

Procidentia is distressing, from friction against clothing and limbs, and from being bathed with urine, often producing ulceration. The indications for treatment are, first, to replace the uterus, and second, to prevent the recurrence of the disorder. The latter comprises mechanical and surgical measures. The mechanical support is by means of pessaries, which are unpleasant, ineffective, and not without danger. In reviewing the various surgical measures proposed. he claims that they all, with the exception of LeFort's, fail to give permanent relief, for two reasons: 1st, they do not elevate the uterus to its normal position and thus facilitate the absorption of hypertrophy and the atrophy which should occur with age; 2d, they do not afford sufficient support in the upper third of the vagina, allow the enlarged organ to sink like a wedge into the nar-

rowed canal, and by pressure cause the absorption of the tissue below, until it is again outside. These causes of failure are obviated by LeFort's operation, which, by constructing a bridge of tissue in the centre of the vagina, supports the uterus. It forms a double vagina. Tracy greatly improved the operation by restoring the perineum at the same time. The only drawback to its invariable performance is that the adhesion of the vaginal walls would greatly complicate delivery.

A case was given in which the operation was performed, which was entirely successful.

After which Dr. John G. Lee, of Philadelphia, read a paper on

Homicides,

in the course of which he said:—

No further back than 1836, a distinguished European scientist and statistician,* in publishing a work, wherein he endeavored to prove that the human race was placed under the influence of regular and periodic causes, affecting not merely its physical qualities, but likewise its actions, these leading to effects equally regular and periodic, made the statement that "Man is born, grows up, and dies, according to certain laws, which have never been properly investigated, either as a whole or in the mode of their mutual reactions." Such a criticism applied now-a-days to the advance of knowledge, and more especially medical science, would be neither true nor just. For in this era of universal progress no branch of science has advanced more rapidly than the study of medicine; gradually enlarging its fields of research, it has pressed into its service and brought under its dominion everything in nature which could aid in any degree whatsoever in its onward stride. Goaded into action by the ceaseless cries of suffering humanity, ardent and indefatigable men have never hesitated to come to the fore and enter the too often thankless career of scientific research; generously forgetful, in many instances, that the work so laboriously performed by them would only be of benefit to future generations, long after they themselves had fallen and perished by the wayside. Yet, though so much has been done, still more remains to be accomplished; to this end, all facts pertaining to the mental and physical existence of the human species are being made the subject of thoughtful study and careful investigation. And, among the many facts which have been attentively observed, the births, marriages and deaths occurring among given groups of population stand foremost in the interest which their study and the practical deductions therefrom have excited. Especially has the cessation of the organic and material life of individuals of the human race been considered a phenomenon of exceeding interest, and been made the subject of almost indefinite investigation, subdivision and classification. Nevertheless, but little work has been done concerning the mode of death to which this paper has the honor of calling your attention. Though indeed, the first death ever mentioned in the Christian history of the world is a violent death, a homicide, or if we read the annals right, a murder, feloniously committed, with malice aforethought.

* A. Suetelet, Sur. l' Homme et le developpment de *des facultés*, ou essai de physique sociale. Bruxelles, 1836.

After a prolonged study of the dark side of life in a great city, I feel convinced that the juxtaposition of wealth and misery, the forcible association of innocence with guilt, and the eternal shock of conflicting interests usual among large aggregations of men, all combine to wear off sooner the thin varnish of a hypocritical society, beneath which man to a certain extent masks his passions, and become important factors in the more or less continual frequent occurrence of criminal homicide in populous centres.

From December 31st, 1871, until January 1st, 1882, out of a total number of 12,936 cases of deaths investigated by the Coroner's office in Philadelphia, 323 cases were deaths from homicidal violence, falling under the Act of Assembly, previously quoted, or an approximate ratio of 27 homicides to every 1000 inquests. As the population of a city annually increases, so naturally the number of homicides might be expected to augment in a more or less similar ratio. Such, however, has not been the fact, as the following figures shows us:—

Years.	*Homicides.*	*Population.*	*Ratio of Homicides to 10,000 Population.*
1872	32	725,000	.44
1873	23	750,000	.30
1874	28	775,000	.35
1875	44	800,000	.55
1876	46	825,504	.55
1877	34	850,856	.39
1878	31	876,118	.35
1879	28	901,380	.31
1880	31	846,980	.36
1881	26	868,000	.29

In no case does the ratio appear to bear any relation to the population. In 1873, for instance, when the lowest number of homicides were committed, the ratio is .30 to 10,000 souls, as against a ratio of 55 for each of the years 1875 and '76, when the greatest number of homicides occurred. Examining into the frequency of homicide, according to color, we find that of the 323 persons who came to their death by criminal violence, at the hands of their fellow-men, 26 were colored people and 297 whites. Of the 26 colored persons, 20 were males, and 6 females, while of the 297 whites, 202 were males and 95 belonged to the weaker sex.

These deaths took place, according to years, in the following order:—

Years.	*Males.*	*Females.*	*Total.*
1872	22	10	32
1873	16	7	23
1874	19	9	28
1875	28	16	44
1876	40	6	46
1877	24	10	34
1878	20	11	31
1879	18	10	28
1880	17	14	31
1881	18	8	26
	222	101	323

The year 1876 showing 46, to 23 occurring in 1873, the males always exceeding the females; the general yearly average for both sexes together being 32.3, and the separate average by sexes, being for the males, 22.2, and 10.01 for the females.

Though, as might be expected, we find that deaths from criminal violence occur more frequently at the period of life when, the bodies and intellect of individuals of the human species being fully matured, their passions are most difficult to control. Yet, from the tenderest age up to far beyond the three-score years and ten usually allotted to human beings, we find men taking the lives of their fellow-creatures.

Period.	*Males.*	*Females.*	*Totals.*
Under 1 year,	15	16	31
1 to 5 years,	5	2	7
5 to 10	3	2	5
10 to 15	3	—	3
15 to 20	13	2	15
20 to 30	53	31	84
30 to 40	56	21	77
40 to 50	42	11	53
50 to 60	17	8	25
60 to 70	13	1	14
70 to 80	—	4	4
80 to 90	1	—	1
Age unknown,	1	3	4
	222	101	323

The highest number being reached between the ages of 20 to 30, and the next highest between 30 to 40 years, then between 40 to 50 years, in fact, just at the time when the struggle for superiority between members of the human family is at its maximum. The fewest lives were destroyed between the ages of 80 to 90 and from 5 to 15 years.

The mortality from homicide forms no exception to the rule proved by mortality tables in general, that the deaths of adults are slightly in excess of the deaths of the minors. There occured 262 violent killing of adults, to 61 deaths of minors; of the minors 39 were males and 22 females.

Figures relating to the condition in life of the victims, are but of passing interest to us; out of the 323, 174 are recorded as being married, 136 were in a state of single blessedness, while the condition of life of the remaining 13 was not determined. 126 of the 174 married persons were males and 48 were females; of the 136 unmarried, 90 were men and 46 women. No correct record of the nativity of those slain having been kept, we are, therefore, unfortunately, without data sufficiently accurate for use in this paper.

Of special interest to us, as physicians, are the anatomico-pathological causes of death, of which we have fourteen different varieties.

First. Homicide from violence, comprising blows, kicks, and other injuries of a contused character, inflicted with nature's weapons, foreign bodies or falls. Of these we have one hundred and twenty-six cases; one hundred and two of which occurred among men, and twenty-four among women. Entering into a more detailed account of the injuries described under this heading, the causes of death, arranged in their order of numerical frequency, were:—

From causes not defined	38
" fracture of the skull	30
" compression of the brain	24
" peritonitis	8
" inflammation and abscess of brain	7
" inflammation of lungs	6
From congestion of the brain	5
" injuries to the head	2
" rupture of the bladder	2
" erysipelas	2
" tetanus	2
" hemorrhage and shock	1
	126

Second. Death from gunshot wounds occurred in 66 cases, 55 of which were males and 12 females, the lesions being specified as follows:—

From causes not stated	37
" wounds of chest	6
" " " heart	6
" " " throat	4
" " " brain	4
" " " lungs	4
" " " abdomen	2
" " " back	2
" " " pulmonary artery	1
	66

Third. Fatal wounds from the use of cutting instruments were 53 in number, 41 being males and 12 females.

From causes not specified	11
" wounds of throat	8
" " " head	7
" " " chest	6
" " " peritoneum	6
" " " femoral artery	3
" " " subclavian artery	2
" " " heart	1
" " " heart and aorta	1
" " " aorta	1
" " " orbital artery	1
" " " ulnar artery	1
" " " crural vein	1
" " " groin	1
" " " arm	1
" " " leg	1
" " " back	1
" " " erysipelas	1
	53

Fourth. Criminal abortion was the cause of 32 deaths, 29 of the victims being recorded as females, the remaining 3 being males. In this form of violence, the deaths of the fœtus do not appear to have been taken into consideration, by the intelligent Coroner's jury, in those cases where the mother perished. Here it may be well to remark, that the crime of abortion does not come under the paragraph of the act of Assembly,* already quoted, but has been made the subject of a separate clause: "If any person shall unlawfully administer to any woman, pregnant or quick with child, or supposed and believed to be pregnant or quick with child, any drug, poison, or any substance whatsoever, or shall unlawfully use any instrument, or other means whatsoever, with the intent to procure the miscarriage of such woman, and such woman, or any child with which she may be quick, shall die in consequence of either of said unlawful acts, the person offending shall be guilty of a felony, and shall be sentenced to pay a fine, not exceeding $500, or to undergo an imprisonment, by

* Act of Assembly, 31st March, 1860.

separate or solitary confinement at labor, not exceeding seven years."

In the following 32 cases death occurred:—

From causes not specifically defined	18
" peritonitis	8
" hemorrhage	2
" violence in utero	2
" pyæmia	2
	32

Fifth. Of one of the most dangerous forms of homicide, the criminal administration of poison, there are only 18 cases recorded; though it can hardly be doubted that a certain number of instances of this variety of crime may either have escaped the notice of the investigating officials, or else have been passed as suicides or accidental poisonings; 7 of the victims were males, and the remaining 11 were females, the deaths resulting from the administration of the following poisons or drugs:—

Names of poison not given	2
Poisoning by chloroform	4
" arsenic	3
" laudanum	2
" alcohol	2
" opium	1
" sulphate of morphia	1
" corrosive sublimate	1
" muriatic acid	1
" podophyllin	1
	18

Sixth. In fourteen instances life was destroyed by suffocation, ten of the victims being males and four females.

Seventh. Of four persons who perished by strangulation, two were males and two females.

Eighth. Two men were found drowned, with such marks of violence upon them as to warrant the supposition that they had met with foul play.

Ninth. Two infants came to their death from criminal neglect.

Tenth. Two aged females were recorded as having been frightened to death.

Eleventh. One infant was starved to death.

Twelfth. One infant was thrown from a window.

Thirteenth. One drunken woman was saturated with coal oil by her insane husband and then set fire to.

Fourteenth. And lastly, one woman was feloniously assaulted, receiving such brutal treatment that she succumbed to the results of her injuries.

Going further into the subject, we find that massed in groups of months, homicides occurred during the past ten years, in the following order:

July	40.	January	26.
April	30.	June	26.
May	30.	November	24.
February	29.	December	23.
September	28.	October	22.
August	27.	March	18.

July, as we see, heading the list and March ending it; the difference, however, in the mortality of several of the intermediate months being so slight that but little importance need be attached to their order of succession in the foregoing table. Though we cannot help but notice that the majority of criminal killings occur in the warm months of the year. This conclusion becoming even more apparent if we examine into the frequency of homicide, by quarters. The deaths by quarters for the past ten years being as follows:

1st Quarter.	*2d Quarter.*	*3d Quarter.*	*4th Quarter.*
73	86	95	69

The 3d and 2d quarters heading the list here, and the 1st and 4th quarters ending it.

While general meteorological phenomena must undoubtedly exert a certain influence over the frequent taking of human life, what their special effects are we are not able to determine; all observations which we were enabled to make having been unsatisfactory in the extreme. Possibly future observations and comparisons, including a greater number of cases and extending over a longer period of time, may some day give us more definite results.

As an epilogue to the preceding figures, it is of interest to know that in only 5 instances was *lex talionis* enforced, and the supreme penalty exacted. During the decade over which our observations extend, only 5 criminals were executed. All 5 were males between the ages of 20 to 40 years; 2 were guilty of wife-murder; 1 destroyed his paramour, and the remaining 2 killed individuals of their own sex,

Glancing at this statistical compilation, the question naturally arises — what end may it serve? Or to what purpose it may be studied? Admitting that the impulsive actions excited by human passions are not subject to special rules and laws; we cannot but define them as being in themselves but the physiological manifestations of certain physical phenomena, which exert a disturbing influence over cerebral action. Thus, the intense cold of our winters, the torrid heat of our summers, combined with the bodily malnutrition, and the cerebral hyperæmia caused by the excessive use of stimulants, so commonly met with among our poorer classes, must all be factors of importance in the calling into existence of the columns of figures above enumerated, and their more or less constant fluctuations. It being now well known that proper hygienic police regulations not alone tend to diminish disease, but also act as a check upon vice and crime. Medical science has under charge, not alone the supervision over physical and mental disease, but it is more and more becoming the duty of this branch of knowledge to study the climacteric, hygienic, psychological, sociological and moral conditions under which man lives, with a view to remedying and preventing the ravages of disease. Why should not moral suasion and expostulation on the part of the medical adviser be combined with sedative treatment, in cases where an excited mind, the result of a hyperæmic cerebral condition, is apt to give way to the fatal hallucination of imaginary grievances? It is easy to see the power which medical men would be able to exercise over many such instances. Again, a proper moral education, with the development of the nobler qualities of human nature, would more and more tend to render impossible and infrequent those most unnatural crimes—abortion and infanticide; cancers which, gnawing at the very vitals of society, demoralize as well as disable our partners in life

by their pernicious physical and mental effects. It is to the prevention of this form of crime that I would, more than to any other, call the attention of this honored body and the medical profession at large, to the end that all who may be found disguising a criminal purpose under the cloak of a noble science be outlawed by the profession, hounded down and pointed out for prosecution when and wherever detected.

In pointing out, thus tersely, the palliative means against the criminal taking of human life, which medical men (the confessors of the XIX century) have at their command, it but remains for me to terminate with the consideration of the legal aspect of the subject. Elsewhere,* I have had occasion to abundantly describe the procedure of our Coroner's courts, as well as the duties of physicians who may be selected by that official to assist him in his investigations; and will therefore pass that portion of the subject, in order to touch upon another of more importance to the medical profession generally.

In this progressive country, where medicine has in all its branches, successfully rivaled the progress of older nations, it is surprising to find that we have as yet no branch of this science taught in regard to its practical application to the law. Austria, Germany, France, Italy, all have their codes and well defined systems for the guidance of practitioners of medicine, when called upon to assist the State; but on this continent, medical jurisprudence, if at all known and practiced, is certainly in its infancy. No chairs, no teachers, or only nominally so, grace our great and well known centres of medical learning, and it is a well established as well as deplorable fact, that even our prominent practitioners shrink from contact with the law, and decline to give the State the benefit of their wisdom and experience. A condition of affairs due only to the fact that they lack the knowledge of their relations thereto, and do not care to place themselves in the situation of being roughly handled and ridiculed by the flippant and discourteous gentlemen who occasionally practice in our courts of law. Owing to our admirable system of non-centralization and the perpetual struggle for autonomy which is continually taking place between different districts, it has not been possible for our legislators to promulgate laws for the establishment of a health-police and medico-legal officers, as they exist in older countries. And while medical jurisprudence cannot be called a science apart, it is to be defined as the application of the exact principles of medical science to the necessities of the State, for the better administration of public justice. In my official position I have been obliged to give much thought and study to this important question, and long ago came to the conclusion that if physicians knew their relations to the law, both the community and the medical profession at large would be the gainers.

I therefore call upon this honored body, which represents the whole medical fraternity of Pennsylvania, to take such action as the circumstances require; and to this effect, I suggest that this Society make it its duty to urge upon medical faculties, members of the profession and students, the high importance of a thorough knowledge of the principles of medical jurisprudence. To further the advancement of which I also suggest that this Society take steps for the creation of a special section, having for its object the science of medical jurisprudence, or State medicine, at the coming meeting of the American Medical Association.

In the evening, at seven o'clock, the Annual Address by the President, Dr. Jacob L. Zeigler, of Mount Joy, was delivered, in the Academy of Music, after which the delegates were handsomely entertained by the citizens, at their homes.

THURSDAY, MAY 11TH.

The Society convened at nine o'clock. Prayer was offered by the Rev. J. Allan Maxwell. After the usual routine business, the following report was offered:—

Report of Committee on Defective Hearing of Locomotive Engineers.

The Chairman of the Committee, Dr. Laurence Turnbull, of Philadelphia, presented the Report of the Committee on Defective Hearing of Locomotive Engineers, Firemen and Conductors. He states that copies of the first report, of 1881, with its resolutions signed by all the members of the committee, had been sent, as directed by this Society, to the presidents and superintendents of all the railroads in the State, also to the members of the Legislature of Pennsylvania. The subject had elicited much interest, and copies of the report had been sent for from various parts of the United States. The committee were happy to state that the Pennsylvania Railroad Company have adopted rules and regulations for the examination of the hearing of all those in their employ, and no doubt other railroads will follow their example, being of interest and importance to them as well as to the traveling public. In the report will be found a comparison of the results of the examination of railroad employés, as compared with another branch of service, namely, the military, showing its importance both to the army and navy of the United States. The reports of the Health Bureaus of the Prussian and Wurtemberg armies are given for 1874–78 showing that during those four years there were removed, from disability on account of ear diseases, 1883 men. Dr. Turnbull has added to the report an appendix containg new cases with facts and observations from patients, and the opinion of engineers of the great utility of these examinations and the proper successful treatment of such defective individuals.

After which the address on Mental Disorders was delivered by Dr. Chas K. Mills, of Philadelphia.

Criminal Lunacy.

The following were among the subjects briefly discussed: The psychology of crime; the classification of criminals; the relation of crime to insanity; the tests of responsibility in criminal cases; the medico-legal methods of determining responsibility; and the disposal of the criminal insane, including under this last head such questions as the punishability of the insane, the necessity of modifying existing laws relating to

*Handbook for Coroners. By John G. Lee, M.D. Philadelphia, 1881.

the insane, and the importance of establishing in Pennsylvania and elsewhere special criminal lunatic asylums.

The psychology of crime is a subject of the highest importance to society, and the increasing inclination to study it in the scientific spirit and by scientific methods, is a sign of advance.

Crime is often, although not always, the result of the organization of the individual, the outcome of the anatomical conformation and physiological development of the brain.

The distinction between vice and crime should always be borne in mind. Technically, crime denotes transgression of the law, while vice refers to the depravity of the individual. The vicious and depraved are not always criminals; and, on the other hand, criminals are not always vicious and depraved. The psychology of vice is really the fundamental question. Vice, according to Bucknill, is probably more infectious and polluting than crime; and while the latter is often the result of insanity, the former is very frequently the cause of it.

Moriz Benedikt, of Vienna, believes that he has discovered the anatomical basis of criminality in a deficient development of the convolutions of the brain, and a consequent excess and tendency to confluence of fissures. Prof. Parker, of Philadelphia, Prof. Osler, of Montreal, Dr. Mills, and others, have conducted investigations which show that these anatomical peculiarities are present in the lower classes of mankind in general.

Crime, as Benedikt indicates, should be viewed as the psychological act of the criminal. Criminals should be studied, not in mass, but as individuals, just as disease should be, and to a large extent is, investigated. Attempts at the classification of criminals by scientific methods have been made recently by Ferri, Krapelin, Lebon, Lacassagne, and others.

A large proportion of criminals are practically insane; they are not of sound brain and mind. In discussing the question of responsibility, however, too much stress is laid upon words. "Sanity" and "insanity" are really relative terms. In some cases responsibility should be made the test of sanity, rather than sanity the test of responsibility. The question of responsibility, when it is an open one, should always be determined by a painstaking, scientific investigation into each individual case.

Criminal responsibility cannot be adjudged by the test of a knowledge of right and wrong. Criminals, sane or insane, can generally distinguish between right and wrong. They often glory in wrong doing, knowing that it is wrongdoing. In other cases, as Dr. Ray puts it, the particular criminal act becomes divorced in the mind of the criminal from crime in the abstract. Even the presence or absence of delusion does not always constitute an absolute test of insanity and responsibility. Sometimes those who are most insane have no delusions; and, on the other hand, sometimes those who are medically and legally sane have temporary delusions. Responsibility must be measured in doubtful cases by the power of control. It is a question of power rather than knowledge. Could he help committing the crime? is the crucial question. Every scientific aid, medical and legal, should be made use of in answering this question correctly, so that neither society, on the one hand, nor the individual on the other, shall be wronged.

Where does the crime of Guiteau belong? Was his crime, as Dr. Allan McLane Hamilton asserts, simply the result of a low state of the morals for which the individual is solely responsible; or was he, by virtue either of his inheritance or his environment, or of both, insane and irresponsible? It is necessary to make a critical study of the case, before coming to a conclusion. The weight of evidence is, on the whole, in favor of his insanity. As to the form of his insanity—whether reasoning mania, as asserted by Hammond, religious monomania, as claimed by Beard, or an early stage of general paralysis of the insane, as suggested by Folsom—there may be some doubt. His case would probably be considered by most modern authorities as a form of affective insanity, or so-called moral insanity. Many proofs of the existence of insanity and insane tendencies in his relatives, direct and collateral, have been adduced. His life, from about his eighteenth year until the period of his crime, was a record of religious fanaticism and delusion, of lust and immorality, of shiftless wanderings, of chimerical enterprises, of impulsive tendencies and of maniacal outbursts. His conduct before, during, and since the trial—eccentric, outrageous, and showing an utter miscomprehension of public opinion—has certainly not been that of a perfectly sane man. When he shot the President, he was evidently under a delusion as to what he called his duty to the country, and as to the effect which the act would have upon his own future.

Expert testimony was not used properly, nor to the best advantage, in the trial of Guiteau. The trials of criminals, particularly criminals whose lives are at stake, should be conducted in a strictly scientific manner. As the law at present is administered, courts of justice, so-called, become too often courts of injustice, or arenas of public display. Experts should not be partisan. A commission of experts should decide as to the insanity of prisoners charged with crime. The work of this commission should be for the court, not for prosecution or defence. This plan has been recommended by our most thoughtful criminalists and alienists.

It may sometimes be proper to punish criminals who are the victims of some of the forms of partial insanity; but it is in such cases above all others that justice should be tempered with mercy, that punishment should be inflicted, as far as possible, with a view to education and reformation. Where neither of these ends can be attained the punishment should be in the form of seclusion or sequestration, with the view of protecting society.

Our laws with reference to the confinement in asylums of criminals acquitted on the ground of insanity should be modified so as to better meet the requirements of justice in special cases.

In cases of homicidal insanity the law might be so framed as to make imprisonment in criminal lunatic asylums for a definite number of years compulsory, and also to put it within the power of the court and juries to make this imprisonment for life.

Capital punishment in the cases of insane criminals probably does more harm than good. If, as seems probable, Guiteau should go to the gallows with the air of a hero and martyr, his example will incite other insane criminals to deeds of violence and blood.

The experience of the country with reference to a case like that of Guiteau cannot fail to forcibly show forth the great neglect of society to properly guard individuals against criminal lunatics of a certain class. This class is made up of those who, in the expressive language of the street and newspapers, are known as "cranks." While the right of both the sane and the insane to liberty should be carefully guarded, the right of the sane to protection from the insane, should be provided for with at least an equal amount of care.

Too many cranks and lunatics are loose in the land. At a recent meeting of the "National Association for the Protection of the Insane and the Prevention of Insanity," held in New York City, January 20th, of the present year, Dr. C. L. Dana made the important statistical statement, that of the more than sixty thousand lunatics in this country, upward of twenty thousand were outside of asylums.

Mistaken pride often leads a family to cover any facts which tend to show the existence of mental derangement in any of its members, even, in some instances, when the insane tendencies are of such a character as to endanger property, limb, or life. Society is to blame in failing to make sufficient provision for the idiotic, imbecile, and insane; and in not providing, by special enactment, and the cultivation of a proper public feeling, for the separation of individuals, dangerous by reason of lunacy or half lunacy, from the rest of the community.

The founding of special criminal lunatic asylums, like those which have been established in England, would be a step in the right direction. Few institutions of this kind are in existence in this country. At Auburn, New York, is a Criminal Insane Asylum, and at Fulton, Missouri, another, not yet completed. In Illinois an asylum for insane convicts is building. Steps are now being taken in Massachusetts to provide for separating insane criminals from the other insane. The State of Pennsylvania has no asylum of this character. The insane of the vicious classes, and the criminal insane, whether tried or untried, convicted or unconvicted, are the inmates of the same asylum with the harmless, the innocent, and the refined; not infrequently the latter are the enforced companions of the former.

Dr. W. H. Daly, of Pittsburg, then presented an address on "Some Questions Relating to Tonsillotomy."

Dr. J. A. Lippincott, of Pittsburg, Pa., followed with a paper on

Abscess of the Orbit.

Post-ocular abscess, though a very formidable, is, happily, a very rare affection, as attested by the statistics of ophthalmic hospitals, both in Europe and in this country. The symptoms are variable within certain limits, and depend partly upon whether periostitis is the initial lesion, and partly upon whether the disease is acute or chronic, sthenic or asthenic. In acute sthenic abscess the constitutional excitement is especially marked. In asthenic cases the febrile symptoms may be of moderate violence. There is pain and tenderness in and about the eye, redness and swelling of the lids, ptosis, and conjunctival chemosis. At first there is no secretion, but a slight muco-purulent discharge is developed later. In the early stage the eyeball appears to occupy its normal position. Very soon, however, it becomes decidedly and suddenly protruded. The exophthalmos may be so extreme that the cornea may be constantly uncovered, and thus exposed to the influence of mechanical irritants. From this cause, added possibly to some disturbance of the trophic nerves, there may be corneal ulceration, and consequent permanent corneal opacity. The axis of the protruded globe is generally directed downward and outward. The pupil is sometimes contracted and sluggish, even when there is no involvement of the tissues of the eyeball proper—a phenomenon which is perhaps explicable by the fact that the sympathetic nerve fibres are more obnoxious to pressure and other injurious influences than the filaments of the oculo-motor. The sight is usually more or less impaired. The visual field is contracted, and phosphenes are observed. The ophthalmoscope may show dilatation and tortuosity of the retinal veins, or serous infiltration of the disk and retina, or a true optic neuritis. Sometimes the impaired vision is due to the stretching of the optic nerve, sometimes to the presence of retro-bulbar neuritis, and sometimes to other intra-ocular conditions than those mentioned above, such as detachment of the retina, irido-choroiditis and panophthalmitis.

The pus sometimes escapes spontaneously through the lids. The globe recedes somewhat into its cavity; and then, in a favorable case, the opening will gradually heal up, and the eye, by degrees, recover more or less completely its functions. The purulent collection, however, may ulcerate through the orbital wall into the antrum, or nose, or into the cranial cavity, and so produce abscess of the brain.

Orbital abscess may be caused traumatically, as by wounds of various kinds and the lodgment of foreign bodies, or by surgical operations on the eye and its appendages. 2d. By exposure to cold and wet. 3d. As a sequela of severe constitutional diseases, such as pyæmia, erysipelas, etc. 4th. By the extension of the inflammatory process from surrounding parts, etc.

The affections most likely to be mistaken for abscess are tumors, particularly aneurismal and cystic; and frequently, in order to avoid errors in diagnosis, recourse must be had to the exploratory puncture. This should be made not with an exploring needle, or slender-bladed knife, but with a fine aspirating needle, since in employing either of the two former instruments the pus is apt to be wiped off by the overlying tissues. Care must be taken not to remove with the aspirator more fluid than is required to settle the diagnosis, because the tension may be thereby considerably diminished, and the difficulty of the subsequent evacuating incision be thus greatly enhanced.

Treatment.—If the case be seen early, and be

of a sthenic character, ice should be applied about the eye, and the antiphlogistic regimen adhered to. If, however, as is the rule, the patient be feeble, supporting treatment ought to be employed, tonics, nutritious diet, etc. On the slightest appearance of suppuration a free incision should be made, and the contents of the abscess evacuated. The knife should be inserted with its plane parallel to the orbital wall, but with the edge turned slightly away from the eyeball. The puncture may be made either in the retro-tarsal fold, or through the upper lid close to the orbital margin. After the incision, an attempt ought to be made to determine the presence or absence of periostitis, by the cautious use of the probe, and by chemical and microscopical examination of the pus. If the track is long, a tent of oiled lint may be inserted. Poultices should be applied, and gentle pressure instituted and maintained. If there be evidence of necrosis, the opening must not be allowed to close up too readily, and antiseptic solutions may be injected with advantage. Of course, if there is any reason to suspect the presence of a for eign body, careful search should be made with the probe, and, if the offending substance be found, it must be promptly cut down upon and removed.

After which Dr. Chas. S. Turnbull, of Philadelphia, read a paper, entitled

Powdered Boracic Acid in the Treatment of Chronic Purulent Inflammation of the Middle Ear—Otorrhœa.

A most gratifying experience in the use of powdered boracic acid in the treatment of chronic purulent inflammation of the tympanal mucous membrane, the constant symptom of which is otorrhœa, has induced him to consider the antiseptic, or what might be more accurately termed, the dry method of treatment. The use of the syringe is, in his practice, a thing of the past, except in so far as employed for the removal of impacted cerumen, foreign bodies, etc. With his father (L. Turnbull), Knapp, Politzer, Gruber, Schrötter and others, he has had unusual facilities during the past twelve years, in which he has been working in the department of otology, for studying purulent diseases of the middle ear; and although having of late followed quite a new departure in aural therapeutics, has been able to record a much larger than ordinary percentage of absolute cures.

The marked success which has attended the modern, dry, antiseptic treatment of cases under his care has led him to advocate its use in this most common form (in this country) of aural disease. Up to about two years ago he felt like avoiding all cases of chronic purulent middle ear inflammation, *i. e.*, otorrhœas. He examined and treated the same with inward misgivings, because he was a non-believer in all the methods in vogue, and had learned by experience to have no faith in the prescribed forms of cleansing, medicating and managing the ears of such of his patients as suffered from chronic otorrhœa. The odor of the usually worse than fetid discharges was at times actually nauseating, and until he commenced to use Platt's chlorides, a most valuable disinfectant and deodorant, could keep neither finger nor instrument free from the characteristic odor.

The practice of either medicine or surgery gives us more or less pleasure in so far as we are successful, and he confesses that although successful to a degree, scarcely a day passed without his feeling chagrined at his utter want of confidence in the ordinary methods of treating chronic purulent discharges from the ear.

Nitrate of silver was used for polypoid granulations, which sprouted and waxed large under its topical stimulation, while solutions of the same in various strengths now and then seemed to act happily and cure certain cases. Carbolic, chromic and acetic acids, sulphate and sulpho-carbolate of zinc, sulphate of cadmium and copper, alum, permanganate of potassium, etc., were in turn used, and found beneficial in only a few cases. Then tannin as a powder was tried, and still more recently when combined with iodoform and thymol. These dried or partially melted and filled the meatus with an ugly, black mass, which acted as an irritating foreign body, and smelled almost as disagreeably as the purulent discharge itself. Thymol was formerly supposed to cover the odor of iodoform. Patients invariably objected to the odor of iodoform, and the so called "deodorized iodoform," as soon as exposed to the air, smells as badly as the original article; and he is of the opinion that if a deodorized iodoform be procured, it will be no longer iodoform, *i. e.*, from a therapeutical standpoint.

Anything new, and in therapeutics especially, as a means of treatment of that most frequent of aural symptoms, "otorrhœa," must call for immediate and specific attention, not only on account of its practical worth, but also for the greater power it gives every physician to control, yes cure, what hitherto has been generally considered an incurable symptom of a disease of the middle ear.

This symptom of disease of the drum cavity (tympanum) is so frequent in this country that, as is often the case, a symptom of a disease is dignified with a specific title, as is the case with the use of the term "otorrhœa," which frequent usage in medical parlance has caused to be understood as synonymous with the now recognized and self defining name, "chronic purulent (or suppurative) inflammation of the middle ear."

The causes which may lead to the existence of a chronic discharge from the ear are well known to the profession.

Whatever causes tend to provoke an inflammation of the mucous membrane lining the middle ear, or its appendages, may lead to a perforation of the membrana tympani, and a discharge from the ear.

In passing, I must mention that it oftenest occurs in infancy, as reflex (tonic) from dentition, it may be, and is, alas! too often a sequence of the dread exanthemata, inherited taints (tubercle and syphilis) by inflammatory extension from the gastro-pulmonary mucous membrane, nasal, post nasal, supra-post-nasal and tubal spaces, and the much vaunted irrigating treatments for the same. Last, but not least, from exposure, carelessness in cleansing the meatus, too forcible blowing of the nose, bathing,

the use of aqueous solutions of castile soap, instillations of olive oil, glycerine, etc., etc. The invariable tendency of most forms of acute purulent inflammation of the middle ear is to get well of themselves, if it were not that the peculiar conditions of the parts provoked the fermentation of stagnant secretions, the formation of pus "from the emigration of bacteria" (Lœwenberg), and the meddlesome interference of those who never pause to consider the conditions present, but pursue time-dishonored plans of guess treatment, which are, as a rule, dependent upon the fragile experience of empiricism. The curing, *i. e.*, the stopping, of a purulent discharge from the ear is the only desideratum, as it would seem, to many sufferers and their medical attendants; he says that, as a rule, it is not the discharge in itself which does harm; it is a too heroic treatment and the subsequent process of cicatrization, which to a greater or lesser extent damages the hearing power. It calls for intelligent management, as well as treatment, so that the functions of the acoustic apparatus (the tympanum and its appendages) may not only be preserved intact but kept in motion.

He has often been met with the objection, and, confesses it is generally well put, "Why dry up the purulent discharge from the ear, since, when suppuration is actually taking place, patients as a rule hear best?" As the discharge ceases in a case of otorrhœa hearing power is, as a rule, materially diminished; but he always makes reply by asking the question: "Which is the better, half a loaf or no loaf?" *i. e.* to stop the discharge and save some hearing which will be permanent, or allow the discharge to continue, and in a greater or less time lose all hearing and become hopelessly deaf. Then, too, if only for the abolition of the disgusting fetor which accompanies such cases, if for nothing else, it is well worth while risking any fancied extension of the inflammatory process. Children with "running ears" are tabooed by their class and playmates. Adults are tolerated, while, self-conscious of this sickening odor from their ears, they shun society, and imagine, not without good cause, that every one is aware of their infirmity. The majority of such patients are generally willing to forego the greater or less amount of loss of hearing power if the offensive discharge can be prevented.

Beyond a doubt a discharging ear is a thorn in the flesh, to be withdrawn in the shortest possible time. Apart from the risk of damage, from a chronic purulent middle-ear inflammation and its otorrhœa, to the hearing and subsequent happiness of the individual, is the undoubted compromised condition of the same unfortunate individual's health. Fetid discharges run down the Eustachian tubes, and poison the system. This is no fancy deduction, but a solemn truth. He points at least ten cases treated within the last six months, where children have presented themselves in a chronic septic condition consequent upon the fact stated. By simple cleansing of the ears and teaching his patients how, by Valsalva's method, to blow the pus outward into the meatus, which he keeps filled with an antiseptic powder and not with cotton, he has met with most gratifying results in these same children, who, from pale and emaciated subjects, have grown into fat and ruddy specimens of humanity.

He has also been met with the objection that "if these discharges from the ear can be stopped, the disease will go to the brain." This idea had its origin in the fact that, heretofore, such heroic measures were used to check the discharge, such caustic solutions were poured into the ears, because no intelligent treatment was employed, and as in the majority of cases no careful ocular inspection of the parts was made, extension of disease to the inner ear or even brain resulted.

Concerning the "insufflation" of powder into the external auditory meatus, he has never been satisfied with the procedure, and says he was always forcibly reminded, on attempting such "insufflation," of the familiar trick of trying to blow a light paper ball into a bottle, which lies on its side. The harder one blows the more certain is the ball to fly out, rather than into the empty bottle. Precisely the same thing occurs when the attempt is made to insufflate powders into the auditory meatus; because the return current carries it all out again, leaving little or none in the meatus. The operator generally gets the most in his face. This point will be appreciated by those who have attempted to employ powdered *iodoform* in this way. Better drop one-fourth of the quantity proposed to be insufflated through a clean speculum. The ear is not to be syringed; it should be cleansed with absorbent cotton. A meatus as tender, and swollen, and excoriated, as they usually are in otorrhœas, can be cleansed with cotton on a probe. It cannot be done by guesswork nor in the dark. Unless the meatus be thoroughly illuminated, every pledget will, in the majority of cases, except in experienced and careful hands, impinge against one or the other side of the wall of the meatus, and cause pain, exudation, etc.

With the forehead mirror adjusted so as to illuminate the meatus, the (outer) cartilaginous portion of the meatus can be thoroughly cleansed. Having gone so far, a speculum is carefully introduced, *illuminating as I proceed*, and through this (unless the meatus be unusually large, when the speculum can be dispensed with) the inner (osseous) portion can be cleansed, down to the membrana-tympani, or even further. So much for the meatus. Now the tympanum must be cleansed. He never attempts to wipe through or into a perforation, but while the patient, by Valsalva's method, blows out any intra-tympanal secretion, wipes it up; or in case of Valsalva's method being impossible or impracticable, he forcibly inflates with Politzer's air douche, and so frees the tympanum by blowing any collection into the external meatus.

If the cleansing be carelessly done more discharge is provoked and an artificial eczema, aggravated by the powder used, defeats the objects sought by a thorough cleansing. As a rule, all applications of any powders become painful when they enter the tympanal cavity, and more especially as they dissolve and run down into the Eustachian tube, through which experience has taught him he dare not allow even pure water to pass, if we in any way consult the comfort of

our patients. Solutions of borax, or better, boracic acid water and glycerine, may be used if the sensitiveness of the parts or the character of the secretions collected therein do not allow the use of the cottoned probe. Experience in the procedure of cleansing is absolutely necessary to success, and the operator must make up his mind to conscientiously don the forehead-mirror and patiently and carefully, under a good illumination, wipe out the meatus.

Having cleansed the meatus, the speculum is to be removed and thoroughly dried, inside as well as outside, and with it in situ, the powder is to be poured into the speculum ad libitum. As the powder is filled into the meatus, through the speculum, it is packed, layer upon layer, not tightly, but firmly, meanwhile gradually withdrawing the speculum until it reaches the mouth of the meatus.

He has given up the syringe as a means of treatment, and has adopted the dry antiseptic method and the exclusive use of *powdered boracic acid*, which, in all chronic cases, he packs and repacks into the meatus until there is a cessation of all discharge.

It is not then that he would claim, for his father any discovery, but simply credit him for having first introduced "Bezold's antiseptic treatment" and perseveringly employed, and while advocating taught the use of, boracic acid powder for the treatment of "otorrhœa."

He described, at length, the exact details of the method which he considers indispensable to a successful use of powdered boracic acid for "otorrhœa," and furthermore, from his own experience and observation, says he has been led to consider this treatment as specific, because he has cured every case of the hundreds he has treated and kept records of for the past three years.

From that time to the present, with but few exceptions, the treatment recommended by Bezold was given a trial, but although Politzer, of Vienna, recommended it highly, and Cassells, of Glasgow, did the same thing, no one was satisfied that the plan of treatment was particularly efficacious, or to be particularly preferred more than many others.

The great mistake, as he has discovered, was in the fact of many experimenters not having observed Bezold's instructions, viz: that *the boracic acid must be nicely powdered.*

Oftentimes one packing is enough. In other cases the packed powder was washed out in a few days, but he persevered, and has always been rewarded for any trouble in filling and repacking. If the discharge ceases, and leaves a hardened mass of discharge and powder, etc., filling the meatus, it must be removed—but not by force, nor by syringing. It must be softened by the instillation of warm *fluid cosmoline* (petroleol), which has the charming recommendation of not becoming rancid by heat, etc. As the mass softens it may be delicately picked loose and blown out of the meatus, by the rubber bag of a Politzer's air douche.

Perforations are healed, and large ones at that; tympanal mucous membrane becomes almost normal in appearance, purulent secretion and all odor is removed, and "running ears" are absolutely cured, by this most valuable antiseptic agent.

Solutions of boracic acid powder, in equal parts of glycerine (which will partly dissolve it) and water, ten to forty grains to the ounce, are to be recommended in acute purulent inflammations of the middle ear, or even in chronic purulent inflammation, especially those occurring in small or unruly children. Such a solution should be warmed, well shaken, and dropped into the ear twice or thrice daily. Where perforations do not heal, on account of their great size, or sclerosis of tympanal mucous membrane, etc., he recommends most highly *powdered boracic acid*, suspended in fluid cosmoline, in varying proportions, warmed, *shaken*, and dropped into such ears once or twice weekly.

Instruments used in aural surgery should be kept in or dusted with powdered boracic acid. He has seen some forms of parasitic otorrhœas transferred from patient to patient, and even with the most careful surgeon a case of aspergillus is often followed by one or more fresh ones, occurring in those of his patients who have been treated about the same time.

In this connection he states that after careful microscopic investigations, and the study of clinical facts pertaining thereto, all the so-called varieties of *aspergillus* which are usually divided, according to their apparent color, into different species, are but one and the same fungus, as it undergoes the successive changes from white, yellow, red, or purple, to black, each representing successive stages of development of the same fruit, which, when fully matured, is *black* (nigricans).

Purulent tuberculous inflammation of the middle ear can be dismissed in a few words: Do not expect to cure such; it cannot be done.

Irritating medicaments, as glycerine, and particularly solutions of castile soap (castile soap solutions have been the cause of chronicity of one-fifth of all the otorrhœas which he has seen in children) the tinctures, oils which become rancid, etc., should be kept out of the ear, and the parts, gently cleaned with absorbent cotton, will, in the majority of cases, cure themselves. If the discharge becomes fetid, antiseptic solutions had better be used as instillations, and under no circumstances does he allow the ear to be syringed. He is using fluid cosmoline entirely in his practice, and as this mineral oil does not become rancid, and so induce parasitic inflammations, it is best for the purpose, and may be conveniently used as a vehicle for powdered boracic acid, powdered extracts of opium and belladonna, morphia, atropia, etc. Boracic acid was first obtained by Homberg (1702) and was formerly known as *sal sedatious hombergi*. It is prepared by adding hydrochloric acid to a hot solution of borax, and crystallizes in white, translucent scales of a white pearly lustre and of a slight acrid taste. Crystallized boracic acid is insoluble in ether, soluble in alcohol, glycerine and slightly in water.

Boracic acid possesses decided antiseptic, antifermentative and deodorant properties. It arrests fermentations and putrefactive decomposition, and is destructive to minute organisms, bacteria vibrios, etc.

Borated cotton is of no use whatever, in aural surgery, the ordinary absolutely clean absorbent cotton being preferable, and especially so when dusted with the dry powdered boracic acid. It is by no means an easy undertaking to pulverize the scaly crystals of boracic acid, and once in the mortar they must be bruised and pounded instead of rubbed, and all careful pharmacists use a bolting cloth to make the powder impalpable; the process at best is a tedious one.

He dwelt at unusual length upon the minutiæ of what he was advocating, *i. e.*, the dry method of treating otorrhœa with powdered boracic acid, since to secure success every step described required to be carefully considered and scrupulously carried out.

This method he most earnestly advocates as well worth a trial, and says, cease syringing ears except for the removal of cerumen and foreign substances, and rely upon powdered boracic acid. He adds, look upon water and glycerine, and the much extolled and cursed castile soap solutions as local irritant poisons. He concludes by stating, that success awaits those who will but adopt this method, which, at first sight apparently arduous, will eventually prove most profitable, both to patient and surgeon.

Following Dr. Turnbull's paper Dr. E. J. Jackson, of West Chester, read a paper on the

Comparative Action of Certain Mydriatic Alkaloids.

Having spoken of the uncertainty prevailing as to whether these drugs were identical in their physiological and therapeutic properties, or as to how they differed, if they did differ, in these respects, reference was made to the assertion of Prof. Landenburg, that daturia, duboisia, and hyoscyamia, are chemically identical in all respects. A study of the physiological action of these three drugs was the basis of the paper. It was found that on frogs the symptoms produced by each of the drugs were, indisposition to move, and general paresis, going on to complete abeyance of voluntary movement, and great diminution of reflex action. This stage, after several hours, gave way to a condition of tetanus, which lasted some days, when the frog had received $\frac{1}{1000}$ of its weight of the alkaloid.

In a series of experiments on himself, the writer had taken $\frac{2}{3}$ of a milligram of each alkaloid hypodermically. This produced a temporary fall, followed by an increase of the pulse rate, by giddiness, dryness of the throat, affection of the eyes, increase of urine, and headache. The subjective symptoms seeming most severe with hyoscyamia and least so with daturia; the pulse rate was equally affected in all cases.

Another series of experiments was to determine their local action on the pupils and accommodation. With the amount of the drug employed (one drop of a $\frac{1}{40\,0\,0}$ solution) dilatation began for daturia at 22 minutes; duboisia at 22 minutes, and hyoscyamia at 21 minutes. The pupils became dilated to the maximum. The accommodation fell from 9.75 dioptrics to 4.8 D. for daturia, 3.2 D. for duboisia, 2.3 D. for hyoscyamia. Recovery of pupil and accommodation occurred simultaneously, for daturia at 6 days, for duboisia at $6\frac{1}{3}$ days, and for hyoscyamia at $6\frac{2}{3}$ days. The above results were the means of three trials with each drug in the same person. The writer thought that whatever value might be set upon the results of this study, it seemed to favor the idea that the three drugs in question were physiologically identical.

Dr. Jos. Hearn, of Philadelphia, then presented a paper on "The Nature and Treatment of Rodent Ulcers," after which the Society adjourned. The proceedings of Thursday afternoon and Friday will be published in our next issue.

Insanity from Drugs.

Dr. H. H. Kane, of the De Quincey Home, Fort Washington, New York City, requests information from the medical profession on the following points:—

1. Have you ever seen any cases of insanity, temporary or permanent, or any deviation from the normal mental or moral state, that could be traced directly to the use of a single large dose, or the continued use of opium, or any of its preparations or alkaloids?
2. Of what type was such insanity? Give symptoms.
3. State patient's age, sex, civil condition, and occupation.
4. What was its duration and result?
5. State color of patient's hair, eyes, and complexion.
6. Was there any hereditary tendency to insanity, or any history of alcoholism, grave nervous disease, or any drug habit in the patient's ancestors?
7. What amount of the drug was used, and for how long a time?
8. What line of treatment was pursued?
9. Please answer the same questions regarding the use of chloral hydrate.
10. Please answer the same questions regarding the use of bromide of potassium, or any other drugs.

Stamps will be returned for all answers. When so requested, communications will be treated confidentially, and a reprint of the article embodying the results of such statistics will be sent to each correspondent.

M. Pasteur.

M. Pasteur has been inaugurated a member of the French Academy. He was received on April 27th, as a successor of the late M. Littre, on whom M. Pasteur, in his reception speech, made a fierce attack. M. Ernest Renan replied to the speech.

Dr. Lamson.

Dr. Lamson, the American physician who fatally poisoned his brother-in-law in England, with aconitia, was hanged April 28th. He virtually confessed his guilt.

—A medical gentleman, known to the readers of this Journal, who proposes going abroad early in July, will, if desired, take professional charge of any invalid who may wish to secure the benefit of a trans-atlantic voyage. Address "J," care of REPORTER.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

A CLINICAL LECTURE ON IDIOCY AND IMBECILITY.

Joint meeting of the Medical Societies of Delaware and Chester Counties,

BY ISAAC N. KERLIN, M.D.,

Medical Superintendent of the Pennsylvania Institution for Feeble-minded Children.

Before introducing to you a number of cases of mental infirmity, all included under the generic term of idiocy, I will touch upon some points preliminary to the study of our cases.

Idiocy is a widely spread and increasing infirmity. Owing to the great reluctance of families to expose to the average census collector the skeletons of their homes, and because of the very imperfect methods adopted, the census statistics are entirely unreliable for any scientific purpose, and we are almost without any sure guide as to the proportion of this class in a community.

The ratio of foreign countries is about as follows: In England 1 to 771 of population; In Scotland 1 to 800 of population; In Sweden 1 to 521 of population.

In the United States the number of idiots, according to the census of 1870, was 24,395, or one idiot or feeble-minded person to every 1376 of population. The great inaccuracy of this return is known to all who have given the subject any attention.

For example: The number of idiots in Illinois, according to the census of 1870, was 1244. A census taken by the Board of Public Charities, in the same year, drawn from correspondence with practicing physicians, made the number 1738; but there were evidences of great unreliability in even the latter: *e. g.*, Cook county, with a population of 350,236, reported no more idiots than Morgan county, with a population of only 28,500. The result of the investigations of the State Board of Charities of Illinois was a published opinion that the number of idiots was greater than the insane, and that the ratio was at least 1 to 867 of the entire population.

If we apply these figures to a few of the States, we have, within their populations, the following numbers of idiots and imbeciles:—

	Population.	*Idiots, etc.*
In Pennsylvania.....	4,282,786	4939
" New Jersey.....	1,130,983	1304
" Indiana.....	1,978,362	2281
" Georgia.....	1,539,048	1775
" Texas.....	1,592,574	1836
" Wisconsin.....	1,315,480	1517
" Michigan.....	1,636,331	1887
" Maryland.....	934,632	1078

These aggregates are more than those of the insane, and more than those of the blind and deaf mutes put together.

Are idiots and imbeciles increasing in numbers at a rate greater than that of the general population? An affirmative statement is made to this inquiry, by the Board of Public Charities of Massachusetts; a decidedly contrary and more hopeful view is taken by statisticians of Great Britain; the difference of opinion may result from a growing precision in Massachusetts in the collection of returns, through which cases of idiocy hitherto unreported are finding their place in the returns of later years. Let us now examine the authorities, for a statement of the nature of idiocy and imbecility

Griesinger says the essential character of all idiotic states is weakness of the intellect; the fundamental disorder he makes a weakness of perception.

Seguin, senior, defined idiocy to be a specific infirmity of the cranio-spinal axis, produced by deficiency of nutrition in utero, and in neo-nati.

Ray, adopting Esquirol's classification of insanity, considers this affection as *defective development of the faculties*, as distinguished from lesion of the faculties *subsequent to their development.*

The Superintendents of American Institutions for the Feeble-minded, in their session at Columbus, in 1877, aware of the inadequacy of any definitions of this complex subject, tried to embrace it under this formula.

*"Idiocy and imbecility are conditions in which there is a want of natural or harmonious development of the mental, active and moral powers of the individual affected, usually associated with some visible defect or infirmity of the physical organization, or with functional anomalies, expressed in various forms and degrees of disordered vital action; there is frequently defect or absence of one or more of the special senses, always irregular or uncertain volition and dullness or absence of sensibility and perception."

The classification of the innumerable forms of idiocy and imbecility is as difficult as a definition. Having recourse to the older authorities on insanity, we encounter variance of opinion, prejudice of statement, and fanciful conceptions, which have affected to a most embarrassing degree the medico-legal literature relating to idiocy and imbecility.

I need but refer to the classification of Hoffbaeur, quoted so largely in Ray, but quoted, too, with the dissent of Esquirol, "that it savors more of the labor of the 'closet,' than of rigid and faithful observation of nature." Indeed, no classification, and no description, can ever be made to fit the subject so accurately as not to omit many individuals and slight some entire groups. Two modern writers—one, Seguin, practical teacher of the idiot, physiologist, metaphysician; the other, Ireland, physician, student, writer—these two offer their classification, in the two unlike but interesting volumes they have published.†

Ireland, the more recent, introduces his classification by saying: "I found it was necessary to have some arrangement in order to say clearly what I wanted to say. Coming to the study of idiocy after having gained some experience in medicine, I have from the beginning viewed it from the standpoint of pathology, and my idea of idiocy is compounded of the following classes, which are generalized from individual, existing idiots, who resemble one another by having the same or similar disease, as they resemble the type of idiocy by having mental deficiency along with a corporal disease:—

1. Genetous idiocy.
2. Microcephalic idiocy.
3. Eclampsic "
4. Epileptic "
5. Hydrocephalic "
6. Paralytic idiocy.
7. Cretinism.
8. Traumatic idiocy.
9. Inflammatory "
10. Idiocy by deprivation.

The faultiness of this classification is evident in the facts, that an individual in any single class may be found in two or more of the other classes, and also that it omits from consideration entirely the essential features of idiocy—the mental deficiency. There is nothing in the mental incompetency of a hydrocephalic idiot, or a paralytic idiot, that is peculiar, one from the other.

But Ireland's classification has a value that should not be lost sight of; it suggests pathological changes or sequences as underlying the infirmity, as no doubt is the case in a great majority of our cases, while it furnishes descriptive titles with certain meanings, for use in writing and illustration

Seguin, the first systematic writer of experience on the subject, assumes that the mental and moral features of idiocy are dependent on conditions of the nervous system, and proposes a classification based upon the seat or location of these underlying physical conditions. "The remote cause or source might be physiological or pathological; the immediate cause was in abnormal conditions, either of the central nervous masses, or in the nervous apparatus radiating from those centres, and which connects them with the individual environments." Proceeding from this, Seguin speaks of the essential forms of idiocy, thus:—

"1st. The chronic affection of a whole or a part of the central nervous masses, which is characterized as *profound idiocy.*

"2d. A partial or total affection of the nervous apparatus, which ramifies through the tissues, and presides over the life of relation, the result of which is *superficial idiocy.*"

He also describes a class of cases, under the head of "backward children," in whom there seems to be a mere *functional torpidity* of the nervous system.

He refers at length to the many maladies with which the different forms of idiocy may be accompanied, speaking of them as *accessory*, and predicating a certain relation between these

* Proceedings of Asso. of Med. Of. of Am. Inst's. F. M. C., p 20. J. B. Lippincott, 18.

† Idiocy: and its Treatment by the Physiological Method. By Edward Seguin, M.D. New York: William Wood & Co., 1866.
On Idiocy and Imbecility. By William W. Ireland, M.D. Edin. London: J. & A. Churchill, 1877.

accessory maladies and the primitive infirmity itself. Dr. H. B. Wilbur, whose experience has been larger than that of any other observer in this country, is "disposed to leave the subject of classification on this physiological basis, where Dr. Seguin placed it more than thirty years ago."

For the common use of our own institution, I have adopted a simple classification, which denotes the grade of the individual, from a somewhat practical standpoint, and which assigns him at once to his rank and associates.

Following Greisinger, I name two conditions of IDIOCY, the *apathetic* and the *excitable;* and under these have classed as idiots those whose intelligence is so slight that we can detect no reasonable basis on which to give anything more than asylum-care so long as they shall live; that is, subjects for habit training only. Next and higher there is a group which, for a better name, may be called *Idio Imbeciles.* I recognize three groups of *Imbeciles.* The lowest group, on the confines of idiocy, are susceptible of some culture of the hand and eye, have a slight command of language, sign or vocal, in communicating their desires, and a low degree of attention, imitation, etc. The middle-grade imbeciles are superior to the low grade in the qualities named, while the high or best grade are possessed of all the attributes of intelligence in a limited degree; they are taught to read and write, in some instances fluently; to calculate minor questions of arithmetic, and approach the lower range of common intelligence in their relations to life as found among the ignorant; in their most advanced grade they are lacking only in those powers of discrimination, judgment and will power, the attributes of a sound man; if they exercise them at all it is in mimicry of associates and superiors, rather than from their personal possession.

Another class of imbecile children is now very distinctly recognized as an increasing product of the excesses and abnormalities of civilization. They may be found more commonly the subjects of neglect, born or drifting into our Almshouses, or quite frequently in the Refuges, where they are sentenced for incorrigible behavior or petty crime. Under the designation of "moral idiots," they figure in some of the works on Insanity; called so because, in many, the perversion seems to be mainly in the display of criminal or vicious intent, without responsibility, or without will power to control the impulse. There is usually a history of family eccentricity, or partial insanity, back of the child. They are denominated cases of Juvenile Insanity.

Such, then, is the simple classification adopted in this Institution.

I. Idiocy. (*a*) Apathetic; (*b*) Excitable.

II. Idio-imbeciles.

III. Imbecility. (*a*) Lower grade; (*b*) Middle grade; (*c*) High grade.

IV. Juvenile Insanity.

I will now present for your observation a number of cases, and in their description will make use of the three classifications I have cited; that of Ireland, pathological; that of Seguin, physiological; and that which rules this Institution in our domestic management of three hundred and fifty inmates. The facts of etiology and treatment will be related as they bear upon individual cases brought before you. The first group of cases I present are those under the denomination of

Apathetic Idiocy.—The type of the class is this helpless, gelatinoid creature, Willie F., 10 years of age, so limp and structureless that, in the language of the nurse, "he doubles in three, like a clothes horse, when lifted from his bed." The only noise that interests him is that of a bell; the only object he ever seems to look at is his hand; he cries when he is hungry; he enjoys being held and rocked; and shows actual delight when bathed; with his great, luminous, soft jet eyes, he reminds one of a seal; perhaps his intelligence is rather below that of a trained seal; it is certainly not that of a babe four weeks old. He is a profound, genetous idiot, with epileptic complication. The oldest sister is deaf and dumb; the second sister is an epileptic; the third child is an idiot of precisely the same grade as this, and is now in our Asylum department; this is the fourth child of the family; both idiots were born club-footed. Four children, all males, died under 17 months of age, and there are younger children, of whom it is alleged that they are weak-minded. Acute phthisis arrested the mother at 41, and put an end to this fearful line of idiocy. Phthisis seems to have existed in the family, and whatever other tendencies to blood degradation there may have been, were intensified by a union in marriage of first cousins. The father is a man of low intelligence, neurotic, and of small stature.

Edith B., aged 10; mute; dwarf; helpless; actuates nothing; her only expression of common wants is a low moan or cry; she rewards the faithful nurse by a smile, and recognizes the epithet "baby," which has been applied to her; she sleeps well, and enjoys a bath; she has passed through critical sicknesses.

Willie, aged $3\frac{1}{2}$; of stronger physique than the others, with excellent teeth, and sensory

perceptions more alert; it is fair to hope that this child may develop under the favorable circumstances of his present surroundings. The child had convulsions during the first six weeks of his life. There is a suspicion of venereal taint in the father's history, who is of consumptive lineage and an invalid. The mother is a faithful domestic, below average intelligence, and had severe convulsions in her infancy.

Ida H., aged 21; genetous, apathetic and dwarf idiot, of a better grade than the three preceding cases; but there is extreme vacuity of intelligence, and absence of any self-hood; utters a few words, and formerly sang snatches of tunes; indeed, tune is not infrequently found in idiots, even of this grade; one whose intelligence is not higher than Ida's has been found automatically singing the difficult passages of L'Africaine, after hearing the music practiced but a few times in a hall of these buildings, quite remote from where she was sitting.

The history of this dwarf is a gross page in etiology. I will quote from a correspondent: "This is the fifth child; the oldest two are sound in mind, but of highly nervous temperament; one sister is deaf and dumb; one brother weak-minded; three died in infancy—one of epilepsy, one was still born, and one died of diarrhœa. The mother and four of her brothers and sisters were all choreic; also the mother's mother; chorea, of a grave character can be traced far back in the mother's ancestry; the mother was an invalid all her married life."

Idiocy, Excitable.—Asher C., æt. 26. Some years ago application was made for the admission of Asher, by a western physician. He thus described him: "He is exceedingly repulsive; in appearance and actions more like a gorilla than a human being; he is kept in a yard or pen, where he runs about in a naked condition; every article of clothing he tears and throws to the hogs. His mental condition seems almost a blank; he has never spoken a word, and his temper is sudden and violent."

We admitted Asher, and believing him to be human, endeavored to make him realize it also; swings, ladders, etc., were used in various ways, as a means of diversion and employment. At first the tearing of clothes was of daily occurrence. Now he seldom tears anything if it be in good condition, but if a button be found off, or a seam ripped, he tears the garment to shreds. He can talk well enough to be understood by any one who is accustomed to him, and will never go to bed without kneeling beside his attendant and going through his form of prayer, the language of which is incomprehensible to the bystander, but his devotion, nevertheless, is touching. He is very helpful in the morning, dressing the smaller and weaker boys of the Asylum with surprising rapidity and dexterity, and is as particular about their garments as about his own; he will never dress a boy in anything that has not all the buttons properly sewed on. He particularly enjoys braiding seven strands of manilla rope for mats, an exercise introduced for the benefit of the lower grade of Asylum inmates. Asher is liable at any time to relapse, and if not under vigilant care, would, in a week, be the "gorilla" described by his family physician.

In the background of many of these cases of excitable idiocy is a family tendency to insanity, and the pathological condition of this sad creature is doubtless that of chronic mania.

When three weeks old Asher had continuous spasms; at four months "was afflicted with head dropsy, and was very low for three weeks; after his recovery was strong physically. There are two brothers and one sister living, who in body and mind have no constitutional peculiarities. A fifth child died of cholera infantum at four months.

"On the father's side there was a great deal of neuralgia and sick headache, on the mother's side paralysis. The grandparents on both sides were addicted to tobacco in excess, and on the father's side to alcoholic excess, as well. The father was addicted moderately to alcoholic drinks, and both parents to tobacco. The father had always been subject to neuralgia, sick headache, and nervousness, was of a very melancholy nature, and though successful in his business and domestic relations, committed suicide in a fit of despondency.

I will call your attention briefly to a few additional cases of excitable idiocy, each illustrative of certain points in this study. Amie F., aged 8 years, mute, wild and vicious, biting any one she can reach, with a chronic nervousness in the act that suggests its irresponsibility. She bit her mother from the time she was conceived; an unwilling and unhappy conception, which the mother admits to have made every effort to abort. A light-headed father, who had run his career of licentiousness, a simple-minded mother, and the unrest of Amie's fœtal life, are circumstances testifying to this sequence; a genetous, excitable idiot.

C. B., aged 20 years, is readily defined as a typical microcephalic idiot, who, but for the discipline she is under, and to which she happily

and easily submits, would be of the excitable variety, destructive, noisy and troublesome.

The cranial measurements are as follows: Fronto-occipital diameter, 5¾ inches; transverse diameter, 4½ inches; greatest circumference, 16 inches.

(To be Continued.)

MARTIN'S BANDAGE IN THE TREATMENT OF FRACTURE OF THE PATELLA.

BY WILLLAM A. BYRD, M.D.,
Of Quincy, Illinois.

Judging from the number of methods devised for the treatment of fracture of the patella that have been published, one must conclude that it is one of the most difficult fractures to treat of all that occur to the osseous framework of the human body. It has been my good fortune to see but few such accidents, and to have the sole treatment of but one. In May, 1876, I published an account, in the New York *Medical Journal*, of, I believe, the first case treated by suture. It was treated successfully by the late Dr. Geo. McClellan, of Philadelphia. I quoted it to condemn it, and it has been quoted by Dr. Hamilton, in his treatise upon "Fractures and Dislocations," sixth edition, in these words: "Dr. Byrd, of Quincy, Ill., says that he had, as early as May, 1876, in the New York *Medical Journal*, called attention to the fact that Dr. Geo. McClellan, of Philadelphia, had made the same operation, only without the carbolic spray, many years ago; but I do not think we need to feel ambitious to establish for ourselves a priority of claim in this matter." During last summer, I witnessed the treatment of this fracture by the silver wire ligature, in one of the largest and best hospitals in London, the operation being done by a most expert operator, with assistants whose reputation was world-wide, and I must say, that after seeing the operation, I have a worse opinion than ever of it. The treatment by Malgaigne's hooks is only less barbarous; and of most of the other methods that have been devised, they are tedious, painful, and uncertain in their results. Perhaps this can be said in a less degree of Dr. Hamilton's method than any other. His method I had decided upon adopting, and the reasons for varying from it will appear in the following history of a case:—

January 9th, 1882, I was called to see Henry Meyer, an athletic laborer, aged 28 years, who was said to have received a sprain of the knee. When I saw him, I found that, while out hunting, his foot had slipped, and in his endeavor to regain his equilibrium, the right patella was fractured at the junction of the middle and lower third. The fragments were separated sufficiently to admit the thumb being placed between them. There was considerable effusion into the joint, with great pain. Not being able to get a leather or shellac-cloth splint at the time, I took an inch-thick pine board, that would extend from the sub-gluteal fold to below the heel, and so shaped it that it was about as wide as the greatest diameter of the leg, except just opposite the joint, where I made projections, so that the bandage, passing around the limb and splint, would exert traction upon the fragments in such a manner as to draw them together (see the cut in Dr. Hamilton's "Fractures and Dislocations," sixth edition, p. 523) and not slip. The splint was well padded, so as to fit the limb comfortably, and the bandage was applied as on page quoted above; "a roller, made of unglazed cotton cloth, is then turned around the leg and splint to within about three inches of the knee, and another from the upper end of the splint, over the splint and thigh, to within three inches of the knee. While an assistant approximates the fragments with his fingers, the surgeon makes two or three turns with a third roller around the limb and splint, close above the knee; after which the roller descends below the knee, and an equal number of circular turns are made close below the lower fragment of the patella; and finally, a succession of oblique and circular turns are made above and below the fragments, which turns are to approach each other in front until the whole of the patella is covered, the last turns being again circular. The dressing now being completed, the rollers are carefully stitched to the cover of the splint, through its whole length, on both sides, and the limb is left supported in the elevated position by a suspending apparatus, or by some other mode which will insure its maintenance in this position." I quote the above for the reader to understand that all Dr. Hamilton's details were carried out, with the exception of the substitution of a pine board for a splint, instead of shellac cloth. This treatment was kept up for a week, but the effusion and swelling not diminishing, I applied a Martin's rubber bandage, instead of the cotton one, from the ankle to the gluteal fold, expecting to get absorption of the effused fluid, and also by the constant elastic pressure to overcome any tendency to spasm in the quadriceps muscle. I had intended to remove the fluid from within the joint, with the aspirator, before applying the bandage, but having removed the bandage from another patient just before calling to see this one, and not having the aspirator with me, I

concluded to apply the bandage, as I had it with me, and if necessary aspirate the next day. When I came to see him the next day the swelling had subsided so much, and he was feeling so comfortable, that I decided not to aspirate. From this time on he made a speedy recovery. At the end of nine weeks I let him get upon his crutches, and to day he walks well on the limb, although there is yet considerable stiffness of the joint. The union is so intimate that it is with the greatest difficulty that the site of the fracture can be made out.

I do not know but that the board splint could be replaced, with advantage to the patient, by one of shellac or of plaster-of-paris, allowing the patient to go upon his crutches at once, applied to the posterior half of the leg, as suggested by Dr. Hamilton. The shellac, on account of its weight, would, of course, be the best. In using the india-rubber bandage it should be taken off at least once a day, and the limb washed, to clean off accumulated epithelial scales and perspiration; the bandage should then be washed dry and re-applied. There can be but little doubt that a great deal if not the whole of the displacement of the fragments is owing to the effusion within the joint, and it would be a good and safe practice to aspirate before applying the bandage; for my views in regard to aspiration of joints I refer the reader to the Baltimore *Independent Practitioner* for September, 1880, or to a very valuable paper by Dr. Wm. Judkins, of Cincinnati, Ohio, published in the New York *Medical Record*, April 8th, 1882.

I really am not sure but that excellent results might be obtained by the treatment of fracture of the patella by the use of Martin's bandage, unaided by any splint, as the elastic pressure, if properly applied, would keep down swelling, and keep the fragments in perfect apposition, if the patient could keep from flexing the leg during both waking and sleeping hours. For fear some one may think I am claiming too much originality in this matter, I will say that to some extent it was foreshadowed by Dr. Edward Borck, of St. Louis, at the last meeting of the Tri-States Medical Society, in that city, in remarks published in the St. Louis *Medical and Surgical Journal*, for January, 1882, upon "Fractures of the Radius; Treatment by Rubber Bandage." These remarks I heard, and Dr. Hamilton himself strikes the key-note of the treatment when he says, in "Fractures and Dislocations," sixth edition, p. 523, "The cotton cloth roller is preferred, especially for the purpose of approximating the fragments, because, if unglazed it yields a little, and adapts itself smoothly to the skin, even sinking down a little just above and below the patella, thus rendering it less liable to slide over. Reversed turns are omitted altogether, because they cause sharp cords where they are folded, and sometimes produce painful constrictions and excoriations." All these reasons apply with more force to the india-rubber bandage. My thanks are due Drs. G. W. Connell and J. B. Shawgo, and Mr. Alexander F. Lee, for their efficient assistance in the treatment of the case.

A CASE OF CHRONIC HYDROCEPHALUS.

BY D. A. HENGST, M.D.,
Of Pittsburg, Pa.

Willie H., aged 11 years, came under my observation in the winter of 1879, with the following history: "Had been a bright and healthy child until the age of two years, when he had an attack of brain fever, lasting about one month, during which time he had several severe convulsions. After this he seemed apparently well until the age of three years, when he had a moderately severe attack of typhoid fever, accompanied by delirium; this attack lasted about four weeks, after which he was in good health for about one year. When about the age of four years, he began to have tremors of the hands and legs, pain in the feet, stiffening gait, feet became stiff, swollen, and sensibility greatly impaired, and could not bring his hands to his mouth. His intellectual faculties at this time were not impaired, but now his head began to enlarge, face broad and aged-looking, eyes sunken, and forehead protruding; he would sit with his head between his knees. From now on he gradually grew worse, and at the age of five years had to be in bed constantly, his head enlarging and the body emaciating, his appetite most of the time being good and bowels regular, but he had no control of his bladder, and there was almost a constant dribbling of urine.

At seven years of age he had convulsions for several days, and after that, at longer and shorter intervals, until his death, which occurred about one month ago.

Three years ago, when I first saw him, his head measured twenty-one inches, in its antero-occipital circumference; body a mere skeleton. with considerable muscular contraction, the forearms being firmly flexed upon the arms, and the feet greatly everted; these contractions increased so that at the time of his death both hip joints were dislocated downward and forward, into the thyroid foramen.

During the six years that he was constantly

confined to bed he also had annoying and troublesome bed-sores, which, on account of the incontinence of the urine, it was impossible to prevent.

The special senses, with the exception of sight, which was very weak, were not impaired. During the last two years of his life the mental faculties were very weak.

After death, which occurred during a convulsion, the post-mortem examination revealed the following state of affairs: Post-mortem rigidity slightly marked: emaciation extreme; length of body forty-five inches, length of legs twenty-four inches, weight of the entire body about twenty-five pounds; circumference of the head, antero-occipital twenty-three inches, biparietal fourteen inches, from root of the nose to the occipital protuberance fourteen inches. On examination of the head found the scalp thin and no subcutaneous tissue; average thickness of the skull about one-tenth of an inch; membranes very tough and firmly adherent to the skull, but not at all to the brain substance. The lateral ventricles were enormously distended and found to contain about fifty ounces of a clear, serous fluid. The brain substance formed a sack varying in thickness from an eighth to half an inch, and was pale and anæmic in appearance; the convolutions and sulci being nearly effaced by the pressure of the fluid. At the base of the brain and in front of the pons varolii was found a tumor about the size of a walnut; it seemed to be attached to the crura cerebri and form part of the floor of the lateral ventricles.

This tumor was examined by my friend, Dr. J. M. Stevenson, of this city, and by him pronounced to be a glioma. The question is, was this tumor a subsequent growth, or did it start about the time the child had the alleged attack of brain fever, at the age of two years?

The nervous symptoms manifested before the enlargement of the head would seem to indicate that the tumor was the primary trouble, and the hydrocephalus produced by the interference with the circulation through the lateral ventricles of the brain.

The treatment in a case like this, of course, amounts to nothing; only palliative measures could be used, and that only for acute symptoms as they arose from time to time.

Cases of hydrocephalus are on record which were said to have been cured, but it is doubtful if they were cured. The duration of this case, nine years, is certainly a long time, the average duration being from two to three years, but cases are reported which have continued even longer than this.

A CASE OF RUPTURE OF THE UTERUS.

Reported at the meeting of Burlington County, New Jersey, Medical Society,

BY W. L. MARTIN, M.D.,

Of Rancocas, N. J.

On the morning of the 15th of fifth month last, I was summoned to attend E. F., aged 31, in what was to be her third confinement. Arriving about 9.30, I found labor progressing naturally; pains coming on rapidly; head beginning to engage in superior strait; os nearly dilated. After waiting considerable time, and the case making slow progress, I gave 30 drops of fl. ext. ergot, feeling that labor had sufficiently advanced at this time to make use of this means to stimulate uterine effort. At a suitable time after this ruptured membranes, and awhile after I gave 30 drops more of ergot, when labor set in with much more vigor than heretofore. When all seemed thus to be going on satisfactorily, and was bidding fair to be soon over, as the head was about to engage in soft parts, there came a complete cessation of all pains. The woman lying in this condition so long, excited my fears that something was wrong, which, upon examination, proved to be the case, as there was found to be a large laceration beginning at the os and extending up into the body of the uterus on the right side. This plainly accounted for the complete cessation of uterine contractions, for in this condition it would be impossible to have contractions of the uterus. Feeling now that the child would have to be delivered without any assistance from the mother, I therefore, through a great deal of persuasion (she having a great dread of instruments), applied my forceps and made every effort my strength would allow, without accomplishing much. Finding the instruments were losing their grasp of the head, I removed them, expecting to apply them again better. But with all the persuasion I could command she would not submit to have them applied again. Knowing now that chloroform or ether would have to be given, I directed the husband to send to Moorestown for an assistant, while I, in the meantime, went home, about two miles away, to come again when the assistant arrived.

About 7 P.M. Dr. T. met me and confirmed my diagnosis of the case. I, therefore, asked him to apply his forceps while I etherized the patient. After she was thus completely insensible to pain, Dr. T. applied his instruments and used all his strength for a considerable length of time, when the forceps slipped from the grasp of the head. A second and third time, with the handles of the instrument bound together with a cord, the

same thing occurred. Becoming exhausted with continued effort, he asked me to change positions with him. I did so, and applied my forceps with no better success than before. So throwing the forceps aside, I turned the child and delivered it very easily in this way.* The placenta was removed immediately after. To prevent a hemorrhage we injected a large dose of ergot into arm. Not an alarming amount of hemorrhage occurred. I gave quinia and opium, combined with other appropriate directions for the night, and left at 10 P.M., when pulse was 120 per minute, small and thready.

16th, 7.30 A.M. Pulse 88, with nausea and vomiting, which had been kept up through the night; but I suppose this was partly due to the anæsthetic. No medicine was retained through the night. I gave oxalate of cerium, and applied sinapisms over the region of the stomach, to control nausea, afterwards subnitrate of bismuth, with other minor things, but still vomiting continued, and nothing retained. 5 P.M. Pulse 80; no pain, but tenderness. Still to give pill of quinine and opium if could be retained.

17th, 7 A M. Pulse 84; no pain; still vomiting. 5 P.M. Pulse 100; considerable pain and somewhat swollen and tympanitic; pill not retained. Injected very near $\frac{2}{3}$ grain of acetate of morphia in arm; ordered turpentine to be applied externally, on piece of flannel, also verat. viride to be given, and the parts to be cleansed with tepid water.

18th, 7.30 A.M. Pulse 72, full and soft; had a good night; no pain, but no difference in swelling of abdomen; gave pill, quinine and opium; continued turpentine, and water injection. 4.15 P.M. Pulse 108; pain came on about two hours ago; vomited again, the first time since last evening; injected $\frac{1}{3}$ grain of morphia; continued turpentine, pills and verat. viride.

19th, A M. Pulse 108; began to vomit again at 5 A.M.; was vomiting when I entered the room; bowels moved some little; had a restless night, especially the latter part of it; same treatment continued, with injection of morphia. 7 P.M. Pulse 104; did not vomit after my visit in the morning until 1 P.M.; continued to vomit during the afternoon; injected morphia; gave calomel with soda; applied blister to abdomen.

20th, A.M. Pulse 100; full; vomiting since 1 o'clock, but as soon as blister drew, nausea and vomiting ceased entirely; bowels were moved freely with calomel; sent for Doctor to meet me; we met at 9 o'clock. He suggested carbolic acid being added to vaginal injection, and the patient to assume the upright position in bed for a few minutes, to favor lochia; other treatment continued as heretofore. 7 P.M. Pulse 96; retains nourishment this evening; same treatment continued.

21st, A.M. Pulse 96; had a good night; breast beginning to enlarge; tympanites about the same. 6.30 P.M. Pulse 104; takes nourishment, eggs, etc.; breast very full.

This ends my notes in the case; but I would state, she gradually continued to convalesce, on from this time, and in about six weeks was out, and now, as I see her, when passing along the road by her premises, attending to her house hold duties as heretofore, she seems in vigorous health.

I have spoken somewhat in detail in reference to the management of this case in the beginning and from day to-day, believing that such cases can be more clearly presented to view in this way than in any other.

* There were no signs of life in the child.

PROCIDENTIA, WITH RIGIDITY OF THE OS, AS A CAUSE OF DEATH IN LABOR.

BY A. SHIMONER, M.D.,
Of Horicon, Wis.

On the 17th of January last I was called by Dr. Halleck, of Juneau, to assist him in a difficult case of confinement.

Upon my arrival the doctor gave me the following history of the case:—

The lady is about thirty-four years of age; primipara; has enjoyed fair health before pregnancy; was married two years ago. I first saw her on the 27th of September last, on account of inability to micturate, complaining of much pain in the abdomen, and unable to keep the erect posture. Upon examination I discovered an enlargement of the abdomen. Proceeding to draw off her urine, I, to my great surprise, felt a large tumor between her thighs, which, upon closer inspection, proved to be the pregnant uterus prolapsed. It protruded about six inches, was about two inches across the os, and about five inches at the fundus. With little difficulty I replaced it, in about ten minutes, after which she got up and passed considerable water, without any difficulty, and felt well till the uterus again prolapsed. From that time up to her labor I replaced the womb five times; at one time it prolapsed down to the knees, carrying down the vagina and bladder. I tried to keep her in bed, but she would get up, in spite of all I would say; would do her housework, running up and down a flight of stairs.

She was taken with abdominal pains on the

10th of January; the pains were not characteristic of uterine contractions. Upon examination, the os was closed, the neck and os were very large and hard; in this condition she remained up to the 15th, during which time she took very little nourishment. The next morning, at three P.M., the os was dilated to about the size of a silver five-cent piece, when she was taken with severe vomiting.

When I arrived, the next afternoon, I found the lady lying on her right side; she was unable to turn on her back, on account of abdominal pain; was very much exhausted, vomiting every minute; pulse was feeble and respiration was accelerated; abdomen was very tender; the child could not be felt through the abdominal walls; the fœtal heart and placental souffle could not be heard; the diameters, both external and internal, of the pelvis were normal; the uterus was low down; the vaginal portion was large and hard; the os could be felt in the centre of the hard lump, and was dilated to about the size of a silver quarter dollar; the head presented, and was at the superior strait. The uterine pains were few and insignificant, but she had a continuous abdominal pain and great tenderness. We gave her an anodyne and stimulants per mouth, but they were rejected. We watched her closely till next morning, but could not perceive any change in the os. Her condition became very critical; exhaustion increased, pulse became more feeble, respiration was more difficult, and vomiting kept on. Seeing that her only hope of recovery was the termination of labor, we came to the conclusion of so doing; but the question arose, what form of operation is here admissible, as the uterine ligaments were totally relaxed, the os too small and very rigid. Thinking that if the size of the fœtal head was diminished sufficiently to enter the os, and with the aid of the anæsthetic it would dilate by gradually drawing it through, I proceeded to perforate the head with Braun's perforator; this I did easily, but then arose the difficulty in applying the cranioclast (Braun's), but after a considerable work I managed to apply it well; when I commenced traction the head elongated, entered the os partly, and was there arrested; the uterus began to descend and had to be held back; the os would not dilate a particle; on account of the softness of the dead child's cranium the bones gave away, and I had to apply the instrument the second time. Seeing the great rigidity of the os, I made two incisions with scissors, which grated like cartilage or scirrhus, and was as tough as leather; even this procedure did no good, and I resorted to a number more, but without avail, as the cranioclast tore the parietal bone, and became loosened. I next tried to produce version, but could not introduce my hand through the os; after enlarging the incisions, which were five or six in number, I managed to grasp the foot, but turning was impossible. Finally, after working hard for about one and a half hours, I succeeded in getting a good hold of the remains of the skull with the cranioclast, made two more incisions, and delivered the child. The placenta was delivered without any trouble, and hemorrhage was slight. The uterus contracted only partially. We immediately washed out the cavity of the uterus with a weak solution of carbolic acid. We gave her stimulants per mouth and hypodermically, but her pulse would not become any stronger, being, as it was before the operation, very feeble and frequent. She regained her consciousness, after the effects of the anæsthetic passed off. But about one hour after the operation she began to sink; pulse became weak, at times imperceptible, extremities cold, and in that condition she expired in a short time.

The afternoon I arrived, I ordered hot baths, but as there was nothing in the house in which it could be given, it was neglected, and I doubt the efficacy of any form of treatment, with exception of incisions, in a case like this. I cannot recall to my mind another similar case, not even similar in disagreeableness, out of about 3000 cases, while at the lying-in department of Prague, Austria. It is fortunate that such confinements are rare.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WM. GOODELL, M.D.,
Professor of Clinical Gynæcology in the University of Pennsylvania.

Reported by WM. H. MORRISON, M.D.

LARGE OVARIAN CYST; DYSMENORRHŒA FROM ANTEFLEXION OF THE WOMB; DILATATION; PROLAPSE OF THE OVARY; HYSTERICAL ATTACKS; TREATMENT OF HYSTERIA.

GENTLEMEN: As this is my last lecture, and I shall not have an opportunity of bringing before you the patient on whom I operated for ovarian tumor last Saturday, I have brought the cyst, and shall say a few words in regard to her condition.

You will remember that on last Wednesday I showed her to you, and I told you that from her appearance I judged that the tumor would weigh somewhere from 90 to 100 pounds, and that I estimated her weight at 80 pounds. I was very nearly correct. The cyst weighed 16 pounds,

and the fluid inside of the cyst weighed 96 pounds, making a total of 112 pounds. The woman, after the operation, weighed 72 pounds. The operation began at 1.15 P.M., and was over at 2.25 P.M. That evening the temperature ran up to 100.4°. The next day it was over 100°, but since then it has not been up to 100°. It has gone up in the evening to 99.8° and down in the morning to 98.6°. Last evening the temperature did not rise to 99.8° but staid at 98.6°. This morning it is 98.4°. She has a good appetite. I feel a strong conviction that she is going to get well.

The treatment was absolute diet for thirty-six hours. As the tumor had reduced her weight to 72 pounds, I did not wait for forty-eight hours to elapse before administering food. I began with milk; at first a teaspoonful, then a dessert-spoonful, then a tablespoonful, and then half a cupful of milk with bread. To-day she is taking eggs, toasted bread and milk.

The diagnosis that I made last week was correct. There was a large mother cyst with a number of small child cysts. Here is the cyst with many of the child cysts still unopened. That is the largest tumor I have ever seen.

I have thought the question over very carefully, whether or not I did right in operating. The operation turned out all right; but that is not the point. Trying to decide what was the best thing to do in this case kept me from having a good night's rest. I think it would have been wiser for me to have aspirated, waited until the cyst began to refill and then have performed the operation. These are my reasons: The extent of the surface of peritoneum exposed was something astonishing; and as you all know, the peritoneum is very vulnerable. Then there were enormous blood vessels which, I think, would have been reduced in size by aspiration. The only really good argument to my mind against aspirating was the one which I mentioned to you; that is, I was afraid that the cyst would refill with a highly albuminous fluid, at the rate of two pounds a day, which would have reduced her very rapidly. I have seen smaller cysts fill up at the rate of over a pound per day.

This is my first experience with enormous tumors. I have weighed them at 66¼ lbs., and in one case we estimated the weight at 70 lbs. Although this tumor was so large, it caused no pain whatever. This is characteristic of ovarian tumors. It simply annoyed her by its weight. She was able to have her bowels moved without much trouble, and had a pretty fine appetite. When she sat down on a chair, she was tolerably comfortable. She has been unable to lie on her back for several months. I did not dare to give ether while she was on her back. I think that she would have died, if I had attempted to do so. I operated with her on her left side, and reached over and made the incision. The abdominal adhesions were pretty firm, but there were no other adhesions, and the stalk was not very large. I consider this by no means a difficult operation. I have frequently had smaller tumors which gave me much more trouble. After the operation, I could almost have wrapped the folds of skin around her body. Her girth previous to the operation was 61¼ inches. The skin is very elastic, and has contracted a great deal, still there is a large cavity.

I presume that I shall get union by the first intention, as I almost always do in these cases. I am a firm believer in the antiseptic dressing. When I used to close up these wounds with wire, without the antiseptic dressing, the wires were always tarnished and black; but when I used wire and the antiseptic dressing, they were just as bright at the time of removal as when they were inserted. That is, to me, a strong argument in favor of the antiseptic dressing. I now use silk instead of wire, but I never have any pus. When a drainage tube is used, we get a little pus at the lower stitches which come near the drainage tube.

Dysmenorrhœa from Anteflexion of the Womb; Dilatation.

The first patient whom I shall bring before you is a woman who has, at her monthlies, suffered the tortures of the damned. She has a very perplexing condition of the cervix. She has a sickle-shaped cervix projecting into the vagina, the vaginal portion of the cervix being the one most bent. Theoretically, there is no doubt that the cutting or bloody operation, as it is termed, is the best one for the relief of this condition. In this operation the posterior wall of the cervix is slit down; a knife is then passed into the womb, cutting the angle which is higher up. This is an operation which I dislike to perform. "The burnt child dreads the fire." As I have told you on a previous occasion, I got badly burnt in performing this operation, having lost a most estimable lady by it. It is an operation with risk, and I never like to perform it unless I feel a firm conviction that it is necessary.

I have the woman under ether, and shall now examine her. I have come prepared to do the cutting operation, but I may simply dilate the cervical canal. Dilatation has been employed in this case a year ago, but it was done without ether, and under such circumstances it must be always imperfectly done. I remove this ring pessary, which I did not put in; she had it when she came to my office last week. She has a retroversion of an anteflexed womb; an anteflexed womb retroverted. What is the meaning of that? Gentlemen of the third year will all understand it. The womb is bent on itself and has not straightened itself, but has bodily fallen over backward, still keeping the anteflexed condition. A retroversion of the anteflexed womb, which means that there is prolapse of the anteflexed womb.

I shall now introduce the sound and see if I can get past the bend. I pass it by what I call the "master's turn," what the French call, applying the phrase to the passage of the catheter, the "*tour de maître*." I pass the sound as far as it will go with the curve posterior, then rotate my hand and depress the handle, and the sound passes into the cavity. The womb measures three inches. This makes me think that forcible dilatation may be successful.

I shall now proceed to dilate. This can be done without the use of the speculum, but it is safer to see what you are doing. This lady is very anxious to have children. She has to work

hard, but at her monthlies she has to go to bed and use morphia by hypodermic injection. I can recommend this operation of dilatation to you with great confidence. As I have said to you on previous occasions, this is rough in appearance, but I cannot recollect any serious inflammation result from it. Occasionally I have had some inflammation, but in these cases it resulted from imprudence on the part of the patient. In doing this operation I use two dilators. The smaller (Eillenger's) is sure to pave the way for the larger and stronger one (Wilson's). The operation can be done with one, but two are better.

Sometimes, in a badly anteflexed womb, you cannot get the dilator beyond the internal os. I worked away for a long time before I hit upon a plan for overcoming this difficulty. The way to do it is this: Take a surgeon's probe, make a sharp turn at the end, so as to pass the bend, then pass that into the womb until the end reaches the fundus. The straight part of the probe now occupies the neck of the womb, compelling it to become straight. You can now introduce the dilator by the side of the probe and then remove the probe. I remember sweating for an hour and a half over a case up town, trying to get this instrument in, and then I only succeeded by using the probe. I now pass the dilator as far as it will go and dilate to a certain point. I remove it and insert it a little further, and so work my way into the cavity of the womb. Having passed the internal os I substitute the larger instrument. It goes in without difficulty.

I cannot promise you that you are going to cure every case, but I can promise you that you will cure the majority, and those who are not cured will be greatly improved. The history is this: you perform the operation, and the woman, at her next monthly, has a great deal of pain and disturbance, for the womb has been bruised, some of the fibres have been torn, and we get, I believe, a fissure, which does not heal at once. It is well to tell the woman that at her first monthly she may have a great deal of trouble, but at the second period she will be surprised at the absence of pain. For a number of months she may go on with ease, and during that time she may become pregnant. That will cure her trouble. After several months have passed she may begin again to have dysmenorrhœa, but I do not recollect a case in which it was as bad as before the operation. I have in some cases been obliged to dilate more than once.

What are the dangers of this operation? If the dilator does not have a shoulder to prevent it from going more than two and a half inches, it may impinge on the fundus and you tear a hole in the womb. I feel satisfied that on two occasions I have torn the womb at the internal os, because, while screwing the handles together, something suddenly gave way, and I had not the slightest difficulty in bringing the handles together. Each of these cases was a great success. Of course, I kept everything to myself, but I watched those cases very closely. I think that while I tore the womb at the internal os. I did not tear the peritoneum, which is elastic, and this prevented any communication with the peritoneal cavity.

My rule is to take away the ether after having dilated the canal and allow the instrument to remain until the woman begins to move and squirm, showing that she feels it. Just before I begin to dilate I slip into the rectum a suppository containing gr. j. of the aqueous extract of opium. The operation requires from fifteen to twenty minutes. The opium will then be commencing to act. I tell the nurse, if the woman suffers much, to use a second suppository at the end of an hour, or better, if she can postpone it that long, at the end of two hours. This is usually the limit to the suppositories. I rarely get along with one. I keep the patient in bed until the soreness leaves her. This evening, as she gets rid of the effects of the opium, she will complain of soreness in the abdomen, and also, perhaps, in the back. If the soreness increases, and the abdomen becomes tender, I lay a poultice over the abdomen, and increase the number of the suppositories, making the number depend upon the amount of pain. The rule is to make her as comfortable as possible, for I firmly believe that opium is one of the best antiphlogistics, especially in pelvic surgery, and that by keeping pain under, we keep inflammation under. If she has a nurse I advise carbolized injections twice daily. I do so for the following reason: As the patient is lying in bed, there will be a little oozing of blood, which will collect in the vagina, form clots, and may become offensive. I never like to have anything offensive in the neighborhood of a newly formed wound; but in this operation there is not much danger of absorption, for in twenty-four hours the little lacerations will granulate, and granulating surfaces absorb only to a limited extent, consequently there is little danger of the absorption of blood, for this does not decompose until at least twenty-four hours have passed. I have occasionally, in an old womb that has been treated by nitrate of silver, made a slight tear of the external os. In performing this operation on one of my patients, a lady in every sense of the word, I made a considerable tear on the right side. She lived at some distance from the city, so I told her that when she went home she should say to her physician, that "I requested you to tell him that I had torn the os in dilating." I was afraid that he might think that she had had a child. If I should examine a woman, who alleged herself to be a virgin, and found such a tear, I should say that she had given birth to a child.

That reminds me of the case of an Irish girl, on whom I operated some three years ago, and removed a large fibroid tumor. It was very large, weighing over a pound. It was so large that I had to divide the perineum on each side to deliver the tumor, but in spite of all, the perineum was torn down almost to the sphincter. I had to put stitches in the perineum and on both sides of it. When she went home there was such a buzz among the old ladies, and from them it extended to the young ones, in her class of life, that I was compelled to write a certificate of her virginity, before these would believe that she had not given birth to a child. There was every evidence that she had never borne a child. Indeed, if she had borne a child, I should probably have been able to deliver the tumor with only a slight laceration.

Prolapse of the Ovary; Hysterical Attacks; Treatment of Hysteria.

The next patient has been lately admitted. She was sent to me with a note from a lady who is eminent for her kindness to the poor, with the request that I should admit her. She is 29 years old; she is pale and anæmic. She has had four children. Her health began to fail after the second labor, which occurred eight years ago. She is regular at her monthly periods. They sometimes last for a day, then stop, and again come on for half a day. She has not lost too much since her marriage, but before that she lost a good deal. She has severe spells, which are so bad that her friends think she will not live through them. These are accompanied by a feeling of suffocation, pain in her heart, pain in her womb and an inability to lie in bed. She has to work very hard, and she tells me that she has a good deal on her mind. The symptoms thus far are those of a neurosis.

I shall now try to find out what is the matter and what can be done for her relief. I find behind the womb a little body, and pressing on this I give the woman great pain. There are some fragments of fæces in the rectum, but when I press backward on this body it slips from under my finger, giving her a great deal of pain. I think, then, that we have a prolapsed ovary, to begin with; further examination confirms me in that belief. There is a slight laceration of the cervix, but that does not cause the trouble of which she complains.

I shall now pass the sound. For the comfort of one or two gentlemen who could not introduce the sound in the ward class the other day, I will tell them that I cannot get this into the womb. The pain that she now complains of is purely nervous, for I am not hurting her at all, as I have not gotten past the internal os. I have now passed it in. The womb is in a good position. It measures 2.5 inches. There is a slight erosion. (The patient was now removed.)

This is a case that nineteen out of twenty physicians would say was suffering from disease of the womb. They would treat her for this erosion. She would go from one to another, and they would make various applications to the womb, but she would get no better. That is not the kind of treatment she needs at present, although that will do some good. The trouble with this woman is that she is below par, her nervous system is exhausted. She says that she has a great deal of trouble. I do not know what it is. Her husband may be intemperate. Her husband may be unfaithful to her. She is in a state of high nerve tension, pale and anæmic. She made a great fuss when I knew that I was not hurting her, but I did hurt her when I pressed on the prolapsed ovary. Why is it prolapsed? It is prolapsed on account of her general condition. All the organs suffer, but the ovaries and the womb, the reproductive apparatus, which is the most exacting during menstrual life, suffer the most. The spinal cord also sympathizes, and we have irregular distribution of blood, congestion and anæmia. In other words, as I sometimes illustrate it, we may have blushings and blanchings, as we have on the surface of the body, occurring in the womb. I am afraid, I become pale; I am ashamed, I grow red. What are these? They are produced by emotion. They are due to mental action on the nerves, and then the action of the nerves on the blood vessels. So it is in this condition. These blushings and blanchings are not on the surface but in the internal organs. That womb is blanching, and again it is blushing. The same thing is occurring in that spinal column, in that heart. This is a mere illustration, but when you ask me what is the disease, what is its pathology, what it really is, I will be hanged if I can tell you. The woman in this nervous condition has no control of herself. Her nerves are not in a state of equilibrium. They are in a state of uncontrol. They are no longer acting harmoniously. One side of the brain is acting more than the other. One set of nerves is acting differently from the others. They are not pulling together, and the result is that we get these conditions of spasms in which her friends think she is going to die. If her friends did not think so she would get over them more quickly. The symptoms are alarming. You will be called to a woman in spasms, and in nine cases out of ten they will be hysterical; but you must not make a mistake. They may be epileptic convulsions, or due to uræmia. There is one symptom which I think that you will not find in other forms of spasms, *i. e.*, tremulousness of the eyelids. The eyelids will be closed but they will be tremulous. When you have this symptom you can safely consider the spasm due to hysteria. I know of no other way of distinguishing hysteria by a glance except the general appearance of the patient, and this can only be learned by experience.

What is the best thing to do in a hysterical convulsion? The best thing to do is to give her a shock, mental or physical. If you are plucky enough to throw a bucket of water over her, she will recover very quickly, but you will probably be shown to the door by the irate father and mother. A good method of producing a shock is to place a piece of ice over the ovarian region or at the nape of the neck. The girl gasps and at once the state of fixity is removed. If you would administer two teaspoonfuls of Hoffman's anodyne, or a drachm of the milk of assafœtida put in the bowel, would probably relieve the condition; but you wish something that will act a little more promptly. My advice is to get down an emetic, if you can. I do not think it possible for any woman to be hysterical when suffering from nausea. If the throat is so rigid that she cannot swallow, give the emetic by the bowel. If you let a woman see that you are not scared worth a cent, she is going to get over her spell very quickly. If she can have the whole house anxious about her, it is nuts for her to crack; and if she can frighten the doctor, it is the biggest nut of all. If you are the old and tried physician of the family, you might remark, so that the woman can hear you, "If she don't get better soon, I shall have to heat that poker red hot and put it on her spine; that spine is in a very bad condition." I venture to say that there is not one woman in twenty who will not begin to get better. I do not advise you to do it, however. It would be like throwing a bucket of water over her. The father would, probably, invite you to the door.

Make a powerful impression. If an emetic fails, use Hoffman's anodyne. This is really a good remedy. It is a diffusible stimulant, more powerful than valerian, with which it is sometimes combined. As I say, give an emetic, if you can, for a woman must be very plucky if she can go through the nausea produced by an emetic and keep up her hysteria.

Extirpation of the Eye.

The Paris correspondent of the *Lancet* thus writes to that Journal:—

Extirpation of the eye is at all times a very serious operation, but it is considered by some ophthalmologists to be positively dangerous in the acute stage of panophthalmitis, particularly when it is complicated with phlegmonous inflammation of the orbit. Manhardt, Knapp, Von Graefe, have recorded some fatal cases after the operation, resulting from cerebral phlebitis, but Dr. Panas, Clinical Professor of Ophthalmology at the Hôtel Dieu, is of opinion that the accidents attributed to the operation are more frequently the result of the malady itself than of the operation. He has performed extirpation several times, for phlegmonous inflammation of the eyeball or of the orbit, and he has had but one death, which, however, was accounted for by a lesion discovered in the orbital bones at the antopsy. Dr. Panas lately performed the operation at the Hôtel Dieu on a young man aged twenty-eight, who was suffering from phlegmonous inflammation of the left orbit in its acute stage, the result of a severe blow with the fist on the eye. The operation was performed under most unfavorable circumstances, as the eye was in full process of suppuration, but it was crowned with success, as the man was able to leave the hospital in three weeks afterwards, quite cured. The following is the mode of operation performed by Dr. Panas for extirpation of the eyeball. After having separated the lids with the dilating forceps he transpierces the ball of the eye behind the ciliary body and the crystalline lens, with a curved needle threaded. This enables him to have a hold on the eye; then, with a pair of curved blunt-pointed scissors, he separates the conjunctiva from the cornea, and cuts through the muscles at their insertion, without even raising them with a hook. Then pulling the eye forward with the thread he cuts through the oblique muscles at their insertion, and the optic nerve at the point of entrance through the sclerotic. In this way he removes the eye perfectly intact, and the operation is certainly more rapidly performed than by the other methods. Dr. Panas considers it also less dangerous, for out of twenty-eight cases in which he had performed the operation in one year, he had never had occasion to record a single accident. His dressing is very simple. He inserts a small bit of soft linen, dipped in almond oil, between the lids, to prevent them sticking together, and then covers the whole with cotton-wool supported by a bandage, and without the intervention of the antiseptic treatment during or after the operation. Indeed, Dr. Panas, who is a great surgeon, uses the antiseptic method on general principle, and does not occupy himself about the rules laid down by Lister and his followers. I once asked an eminent French surgeon what he thought of Listerism. He said there was one good thing in it. It makes surgeons more careful with their dressings, but that the virtues ascribed to the system were as mythical as the creatures it was intended to destroy.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Effects of Alcohol on the Brain," a paper intended for popular instruction, read by J. B. Sullivan before the Stanton Excelsior Club.

——We have received, with the compliments of Dr. Reeves, a copy of the Act amending the Code of West Virginia, concerning the Public Health. It is very exhaustive and thoroughly covers the ground.

——Mr. George S. Davis, the publisher, announces that he will have ready, within two months, the translation of Dr. L. Lewin's great work on "Drugs." This translation has been made at the request of the author and under his supervision.

——"Compensating Conditions in the Causation of Sickness," by Milton Chase, M.D., of Otsego. This is a reprint, from the Annual Report of the Michigan State Board of Health for 1881, of a paper read at a Sanitary Convention at Battle Creek, March 29th, 1881.

BOOK NOTICES.

Transactions of the Medical Society of Pennsylvania, at its thirty-second annual session, held at Lancaster May 1881. Published by the Society.

Every physician in the State ought to have this volume on his book shelf; he ought, indeed, to make it a point each year to procure a copy of the proceedings, since their accumulated contents will furnish him at any time a history of the profession of his State.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00

PHILADELPHIA, PA.

SPECIAL HOSPITALS FOR INFECTIOUS DISEASES.

Since we have realized the fact that scarlet fever, diphtheria, measles and like diseases are equally as infectious and contagious as smallpox, and since we know that the after effects of these diseases are in many cases infinitely more serious; so then do we have the same arguments for the establishment of special hospitals for these diseases that we have in the case of the more loathsome disease. Our only reason for setting apart a special building for smallpox patients, and compelling such to go there, is because we realize that isolation is one of the most important means of preventing the spread of the disease and checking its ravages. Since we know that isolation is equally potent to check the spread of all contagious or infectious diseases, there should be no hesitancy in preparing suitable buildings and enacting laws to guide the isolation of all patients affected with any infectious disease. There is one fact we must stare in the face. So long as contagious diseases, in the persons of their victims, are allowed to mingle with their fellows, so long will they be communicated from one to another, and so long will they continue to afflict and devastate the people of the world. There is but one way in which we can hope to stifle the wonderful vitality of these disease germs. We must remove them and the body in which they reside to some secluded spot, where they will not find new material upon which to inflict their pestilential presence, when their vitality will utimately become exhausted.

It would, no doubt, seem like a hardship to some, were they to be compelled to send those near and dear to them to a public hospital, when taken with scarlet fever, diphtheria, etc. But we must ever remember that one of the greatest foundations of social prosperity and advancement is the principle of the greatest good of the greatest number. This isolation will redound to the material advantage of the greatest number, therefore, it should not be objected to by the few, who may become so afflicted. Again, remember the golden rule, "Do unto others, etc." We would all like to have *other* cases of contagious diseases sent to the hospital, but would prefer to have an exception in our own cases. This principle is erroneous and selfish. It is a very important duty that physicians owe to society, to instruct those to whom their advice is potent, about the necessity of isolation, and to advise that every case be so isolated. The question of special hospitals was brought before the New York State Medical Society at its last meeting, by Dr. Jacobi, and the matter is now being agitated in New York. Several prominent philanthropists of that city have the matter in hand, and it promises soon to assume a tangible shape. In addition to the isolation, there is another important point to be considered. By erecting good buildings, in healthy locations, with their sanitary arrangements perfect, the majority of the patients would actually be surrounded by better hygienic influences than they would be at home; which would naturally tend to reduce the rate of mortality. Private rooms, handsomely furnished, with all home comforts, could be provided for those able to pay; while to the poorer classes, nice, clean,

well ventilated and lighted wards, with good medical attendance, and kind and careful nursing, would constitute a better home, and supply much more favorable conditions for recovery than the majority of them could command in their own houses. This is a matter of the greatest moment, and its careful and attentive consideration is recommended to physicians and public-spirited citizens everywhere.

News and Miscellany.

Medical Society of the State of Pennsylvania.

THIRTY-THIRD ANNUAL SESSION.

(*Continued from page* 532).

On the Nature and Treatment of Rodent Ulcers.

The object of Dr. Hearn's paper was to call the attention of general practitioners to the early recognition and treatment of this disease. The term, he claims, is a misnomer. The ulceration is secondary to the primary cancerous deposit. The deposit *always takes place in the skin*, generally engrafting itself upon a mole, wart, or some injury or abrasion. It differs from epithelioma, which may commence in the skin, also in the tissues beneath the skin. It differs from ordinary ulcers in that it is progressive and never heals. It differs from syphilitic ulcers in that it is single and never multiple. Although usually a senile disease it may occur in younger persons.

The ulcer is generally painless, unless it involves nerves, and is the tardiest of all forms of cancer in destroying life; sometimes lasting twenty or more years. The lymphatics of the neighborhood are never involved. Its usual location is on the face, although it may occur on the hands, vagina, or elsewhere.

The appearance of the ulcer, in rodent cancer, is that of a sore, with hard, ragged edges, and a somewhat solid base. Rodent cancer is not necessarily a malignant disease, the term cancer being an anatomical, while malignant is a clinical distinction. Properly treated in the early stage it may be radically cured. The usual exemption from glandular enlargement constitutes the fundamental distinction between rodent and malignant disease.

The *treatment* of this disease in the early stage is the complete destruction of the ulcer, even a little beyond its edges, using caustic or the knife. Caustics have failed often, because the edges and the base as well have never been entirely destroyed. This is why opprobrium has been cast upon the "caustic plan" of treatment.

Many patients will not submit to the use of the knife in the early stage of the disease, hence caustics can be as effectively used, especially if the ulcer be no larger than a silver half dollar. Those of a larger size call for the use of both knife and caustic.

The Doctor preferred the use of caustic potash, in the local treatment of the smaller ulcers, although other caustics may be equally efficacious. In using the escharotics, the entire surface, *i. e.*, base and edges, must be thoroughly cauterized. With the larger varieties, especially those involving the orbit, after the use of the knife the opening is to be packed with paste of chloride of zinc. This has for its object the destruction of any remaining cells which might have been missed in using the knife.

Another caustic to which the Doctor was especially anxious to call the attention of the profession was ethylate of sodium, which he thinks possesses to a much greater degree than other caustics the power it has of destroying diseased cells, and leaving healthy ones unharmed. It is more particularly adapted to superficial ulcers, especially in those cases where they occur on the nose or forehead, in which, on account of deformity, he dislikes to use a stronger caustic. He paints the affected parts freely, knowing that in a few days a slough will occur and leave the parts beneath entirely healed.

Dr. Alfred T. Livingstone, of Philadelphia, presented a paper embodying some

Suggestions Relating to Some Modifications of the Pennsylvania State Lunacy Laws.

Some of the principal points made were the necessity for greater care in the preparation of statements regarding the condition of insane patients, and the making of affidavits in cases of insanity; the importance of physicians granting certificates examining the patient independently. Further, the advisability of appointing a special official for the inspection of private and public insane asylums, and the advantage of the home treatment of the insane.

When the Society reconvened on Thursday, at 2 P.M., Dr. John L. Atlee, of Lancaster, Chairman of the Nominating Committee, made the following report of officers for the ensuing year:

President, Dr. Wm. Varian, of Titusville. First Vice President, Dr. A. Hewson, of Philadelphia. Second Vice President, Dr. E. P. Allen, of Athens. Third Vice President, Dr. Alvin Thayer, of Erie. Fourth Vice President, Dr. A. M. Miller, of Bird in-hand. Permanent Secretary, Dr. Wm. B. Atkinson, Philadelphia. Recording Secretary, Dr. Edward Jackson, West Chester. Corresponding Secretary, Dr. John G. Lee, Philadelphia. Treasurer, Dr. Benjamin Lee, Philadelphia. Committee of Publication, Drs. Wm. B Atkinson, Benjamin Lee and Charles S. Turnbull, of Philadelphia, and Edward Jackson, of West Chester. Dr. J. J. Sibbett, Chairman Committee on Medical Legislation, submitted a report in reference to the act of the Legislature providing for the registration of all practitioners of medicine and surgery. He said that after addressing county medical societies and prothonotaries in counties where there are no societies, responses were received from 46 out of 67 counties in the State. From these it appeared that out of a total of some 2200 registered, 674 were graduates of the University of Pennsylvania and 1020 from the Jefferson Medical College, while 619 were not graduates of any college. In Philadelphia, out of 1554 registered 220 are homœopaths, and 210 from institutions outside of the University of Pennsylvania and the Jefferson Medical College; 48 are registered who

are stated to be without any regular medical education. The Committee report that the enforcement of the registration act is the first duty of the profession, and a committee should be appointed in each county medical society to supervise the work.

Dr. A. L. Kennedy stated that cinchona could be successfully cultivated within the United States, and said that the new Commissioner of Agriculture was in favor of the enterprise, and that the Society should encourage him.

At 2.30 P.M. the Address in Hygiene was delivered by Dr. W. F. Muhlenberg, of Reading, who chose for his subject "Micro-germs;" the address is so well worthy of publication in full that we reserve it for a future issue, since it is too long for our limited space.

A paper was read by Dr. Wm. S. Little, entitled

Subjective Traumatism of the Eye;

Its Importance when the Question of Sympathetic Irritation or Sympathetic Ophthalmia Arises.

Traumatism of the body is strictly objective. Conditions arise in organs or parts of the body which impair their action and function as seriously as by foreign bodies; this is subjective traumatism. The eye presents for observation and treatment, then, two forms of traumatism.

Objective traumatism of the eye is due to injuries by foreign bodies and effects in the eye by general disease, by which vision is impaired, lost, or the organ destroyed, with or without sympathetic ophthalmia. Subjective traumatism is due to the condition in the eye resulting from the strain occasioned by optical defects, impairment of vision resulting from, or inflammatory action and diseased condition produced by, strain on the cornea of the eye. Objective traumatism is chronologically of first importance, as ophthalmic surgery has longer been studied than ophthalmic medicine and the correction of optical defects.

Statistics of ophthalmic work afford the following: 17.7 per cent. is operative; 4.5 per cent. of these for enucleation of the eye, for some of the many forms of objective traumatism; this is from the report of the Dublin Institution for Healing Diseases of the Eye. Subjective traumatism has a larger field.

Dr. Risley's (of Philadelphia) statistics give only 12.28 per cent. of eyes that are emmetropic; myopic 19.33 per cent.; hypermetropic 66.84 per cent. These statistics are much higher than those of Lorenz and Derby, of New York, and Erbmann, of St. Petersburg.

The abuse of the muscular vascular tunic of the eye in obtaining vision among persons with ametropic eyes, leads to subjective traumatism and serious results to vision and the tunic of the eye ensue, as serious as occur in the small field of objective traumatism, which in emmetropic eyes produces only objective traumatism, while objective traumatism occurring in ametropic eyes yields more serious results, and subjecto-objective or objecto-subjective traumatism arises.

The emmetropic eye is structurally healthy, though Dr. Risley states 20 per cent. are unhealthy; yet 80 per cent., according to his statistics, remain healthy and only subject to subjective traumatism. The emmetropic eye is free from disease, and when diseased readily cured, or when injured by foreign bodies is less liable to take on sympathetic irritation or sympathetic ophthalmia of the other eye, it b ing emmetropic also.

The correction of optical defects is essential in diseased eyes or the condition of emmetropia must be known to exist.

If this is so essential in diseased eyes or in therapeutical treatment, it becomes far more important when surgery is applied, as after operation all optical defects should be corrected.

When the question of sympathetic irritation or sympathetic ophthalmia arises, the necessity of finding out whether it is due to the objectively traumatized eye or whether it is due to the optical defect in the eye not injured, is necessary, so as not to enucleate an eye unnecessarily, or if it be enucleated still correct the optical defect in the remaining eye, so as to do away with all forms of traumatism.

Cases are reported in support of all the conditions that are experienced in the paper as occurring in the Eye Department of the Jefferson Medical College Hospital, under the care of Prof. Wm. Thomson, Ophthalmic Surgeon to the Hospital and the writer of the paper, and also those in his private case work.

Dr. Leffmann, of Philadelphia, read a paper on the "Medical Relations of the

Prevailing Food Adulterations.

The paper began with a notice of the inaccuracy of the general newspaper agitation on the subject, and pointed out that the general character of adulteration was not of a nature calculated to actively spread disease. Especial attention was given to glucose and oleomargarine, as important substitutes for common articles of food. It was pointed out that the first of these bodies was so much like common sugar, and the second so much like common butter, that no serious injury could result from the extensive use of either. The impurities present in glucose, although sometimes spoken of with alarm, are really of little importance, and the difference between the chemical composition of butter and oleomargarine consisting merely in the absence from the latter of a few per cent. of butyric acid, such difference cannot be of any consequence in a dietetic point of view. The use of glucose in fermented liquid, as a substitute for malt, was shown to be of absolutely no consequence; for the sugar of malt and other fermenting liquids is substantially the same as that made by the artificial method, and, of course, the alcohol formed from either is identical. Specimens of granulated glucose and of table sugar largely adulterated with it were shown, and a test for the detection of such adulteration was described. This consists in boiling a solution of the sugar with a little sodium carbonate, when a yellow color indicates glucose.

Note was also made of the now frequently published statements as to the use of such bodies as ground talc and other insoluble powders as a means of adulterating flour, butter, candies, etc. Dr. Leffmann stated that, in spite of the frequency of these statements, he never was able to obtain a specimen of food adulterated with such materials, and he doubted the extended use

of them. It was pointed out, however, that some inferior kinds of groceries are made up of sweepings and refuse, and such articles will be marked by a rather high percentage of mineral matter. Of this kind was a sample of cheap ground coffee, which was found to contain about fourteen per cent. ash, while the good article gave only about four per cent. The extensive use of starch and plaster of Paris in candies was stated to have been amply confirmed by analyses, and in reference to the use of poisonous colors, lead chromate (chrome yellow) was the only objectionable substance of at all frequent occurrence. In conclusion, the author of the paper stated emphatically his conviction that at present no necessity existed for specially enlarging the power of the State or National governments in this matter, as the wrong is mostly of a commercial nature, and probably entirely controllable through the ordinary channels of justice and the laws as now existing.

A paper on

Puerperal Malarial Fever

was read by Beriah E. Mossman, M.D., of Greenville.

The attention of medical men who reside in malarial regions has of late years been directed to the subject of the influence of malarial or telluric poison upon the lying-in woman. The result of careful clinical investigations has been to secure abundant testimony, which goes to prove that during that period the poison will develop itself with such symptoms and conditions as to justify the conclusion that malarial fever is one of the diseases incident to childbed, particularly in localities where malarial diseases prevail. Although the term *puerperal malarial* fever is not included in medical nomenclature, it is, in my opinion, an appropriate one, and as time passes, and the disease is better understood, it will meet with recognition by practitioners and occupy a place in the medical literature of the progressive future.

The views which I express upon the subject in this paper are those arrived at from my own study and observations during an experience of over eighteen years' practice in a highly malarial region, during which time I have treated quite a number of these cases in my own practice, and have had the privilege of seeing others in the practice of cotemporary physicians.

I have been unable to find any literature upon the subject, with the single exception of an excellent paper written by Dr. Barker, and published in the *American Journal of Obstetrics*, April, 1880. The publication of Dr. Barker's paper anticipated me, as I was at that time preparing an article for publication upon the same subject.

It is a disease not infrequently met with, and bears a striking resemblance in its symptoms to other diseases of a more serious nature, incident to the puerperal state, in which local phlegmasia exists. Hence. it is important that it should be recognized by the practitioner as early as possible whenever met with, for upon a correct diagnosis will depend intelligent and successful treatment. The occurrence of chills, followed with high temperature, at such a time, cannot fail to cause alarm and anxiety in the mind of any person around the patient, as the great mortality of puerperal diseases is well known. Hence, if a chill has occurred, followed by high fever, and the case can be promptly pronounced a malarial disease, it will save the friends and all those near and dear to the patient a great deal of anxiety.

After an account of the etiology of the disease, Dr. M. describes the symptoms, clinically. Cases of puerperal malarial fever differ greatly in the severity of symptoms, although every case will have paroxysms of more or less prominence, recurring at moderately regular intervals. These paroxysms will be followed with periods of apyrexia, or if not of complete absence of fever, the temperature will be much lower and a general letting up of all symptoms. The most prominent symptoms, according to Dr. Barker, are "chills, sometimes very slight, often a temperature near two degrees higher than is found in the beginning of any other puerperal disease, a rapid pulse, followed by greater prostration than is usual with other diseases during this period. Then. in these cases, where the disease first manifests itself by such an explosion of striking and alarming symptoms, there is a remarkable remission on the following day, so that the obstetrical attendant flatters himself that the attack is ephemeral, and that his treatment has been most wise and successful; but this delusion is removed, one, two or three days after, by a recurrence of the attack, but generally less severe. But the succession of phenomena first described only appear in typical cases. I am disposed to believe that in a large majority of cases, three or four days before the explosion, the patient finds herself depressed by a general malaise, more or less pain in the head, back and bones; insomnia, thirst and loss of appetite; and when the disease is developed, the chills are less severe, the temperature not so high, the pulse less rapid and the remissions less marked."

My experience has been that some cases commence without any of the prodromes of malarial fever being present to mark the approach of the chill, and the attack may begin very soon after delivery, in a few hours, or during the first day. Again, the chill may be very slight at first, indeed, so slight as to entirely escape the notice of the patient and the nurse, and when this is the case the first warning of the existence of the disease will be a sudden rise in temperature, but at no time reaching the same height as is the case when the chill is severe and prolonged. Diarrhœa, pain in the bowels, offensive or suppressed lochia are conditions that are sometimes present, and secondary hemorrhage is likely to occur in cases where the disease continues any length of time, and will not succumb to treatment. Delirium is a symptom I have seen, but most generally in those cases where there was suppression of the lochia, or it was scant and offensive. In these cases I have observed that the temperature mostly kept high, the pulse fast, during the period when the intermission should occur; at the same time the skin would be moist. It has been a matter of doubt in my mind whether these symptoms just mentioned were not mainly due to poisoning from absorption of septic matter. But there may be suppression of the lochia

in these cases without any delirium or symptoms of blood-poisoning. In most cases of suppression, where it occurs soon after the delivery, it generally returns soon after the disease is cured.

Puerperal malarial fever may follow successive confinements in the same patient, as was the case with one lady whom I attended after her last two confinements. This was exceptionally worthy of notice from the fact that the first time she had the disease the chill commenced in about one hour after labor had been completed, a remarkably early period of development.

The temperature may keep up quite evenly, the pulse beat high for two or three days, but close observation will show periods of slight intermission, and an absence of pain and tenderness in the bones should lead us to the conclusion that the case is malarial. If quinia is given in full doses at such times as the symptoms are least aggravated, or, in other words, at the period of slight intermission, and its administration is followed by moisture of the skin, slowing of the heart's action, and rapid falling of temperature, the case is undoubtedly, other symptoms corroborating, puerperal malarial fever. Although when these conditions exist it is difficult to determine the true nature of the case, I believe that by careful watching and study a correct diagnosis can be made.

The earliest period at which the disease has made its appearance, in my experience, was in the first case I have related in this paper, in about one hour after delivery. This patient lived in a malarial section of the city, and had had an attack of intermittent fever several months before, but at the time of confinement, and during the period of pregnancy, was unusually well and free from any of the symptoms that ordinarily precede the advent of malarial diseases.

I am inclined to believe that most cases will commence at about the sixth or seventh day.

The second case I have given shows that the intermittent attack, after having been brought under submission by appropriate treatment, recurred on the fourteenth day. This is an important fact, and should not be forgotten in the treatment of cases.

The disease may occur at any time during the puerperal state, which includes the period of the first month after delivery, or until the physiological conditions have been restored.

Diagnosis.—The remarkable resemblance that puerperal malarial fever, in many instances, bears to the formidable inflammatory diseases, or those of septic origin, that occur during the first month of parturition will cause the medical attendant some trouble to decide, with any degree of certainty, what disease he has to battle with. In some cases it will be likely impossible to make a diagnosis until the stages have fully developed.

Dr. Barker says, in speaking of differentiation, "That in malarial fever a fall of temperature of three or four degrees is always attended with a corresponding decline of other symptoms, which is not the fact in septicæmia, and the latter is rarely accompanied by pain of the head, back, or limbs. The sensibilities are blunted instead of being morbidly acute.

When the disease first manifests itself, after the sixth or eighth day, I think, however closely the symptoms may resemble septicæmia, the fear of this may, with a considerable degree of certainty, be dismissed."

There is danger, however, that it may be confounded with puerperal fever; but if it is remembered that puerperal fever is a disease that generally begins on or about the second or third day, such a mistake is not likely to happen very often. Further, puerperal fever, after the onset, pursues a steady course, and is not subject to febrile paroxysms, followed by remissions of high temperature, and these recurring at regular periods. There is most always pain, severe and lancinating, confined to the hypogastrium, the bowels soon become swollen, excessively tender to the touch, and the patient lies with the limbs drawn up; in many cases the weight of the bedclothes cannot be borne.

From septic metritis, cellulitis, or phlebitis it can, I believe, be easily distinguished, as the characteristic symptoms of these diseases in connection with the physical condition will reveal the true nature of the disease upon investigation. I am well aware that in some cases of inflammatory diseases the symptoms are so marked, and the local trouble so slight, as to amount to nothing more than tenderness upon pressure over the womb. In cases of doubt, if the attendant is watchful, and the disease be malarial fever, it will, without doubt, sooner or later show its true nature by falling of temperature, decline of the other symptoms, and moisture of the skin.

Treatment.—There is but one known remedy that is universally admitted to be a sure cure or specific for malarial fevers, and that is quinine. It should be given in full doses from the first. It is my practice to give fifteen to twenty grains upon the first indication of a fall of temperature. When the stomach rejects it, as sometimes happens when given in large doses, it will be best to combine it with a little opium, or administer it by enema. It should always be borne in mind that the disease is liable to return after having been checked, and the quinine should be continued for several weeks, in smaller doses. Attention should be paid to all hygienic conditions, and the body sponged daily with alcohol and water.

Intra-nasal Surgery.

Dr. Carl Seiler, of Philadelphia, read a paper on Intra-nasal Surgery. In it he recounted some of the surgical operations lately introduced for the relief of nasal stenosis, which he considers the prime cause of the symptoms of nasal catarrh. The obstructions to breathing through the nose which could be removed by surgical means were divided into two classes, viz., those produced by swelling or enlargement of the mucous membrane and by soft tumors growing from the mucous membrane, and into hard, bony or cartilaginous projections into the nasal cavities. The former class was again divided into permanent and temporary stenosis or obstructions. The Doctor then went on to describe the operations advisable for the removal of these obstructions, and said that he had found that the most satisfactory and at the same time least painful method of removing those swellings which are situated at the anterior portion of the turbinated bones, and which are called anterior hypertrophies, was by

means of the galvano-cautery knife; describing the different steps of the operation. He said that it is of great importance in this operation to have the platinum loop at the proper temperature, for if it is too hot, considerable bleeding will follow the incision, and if too cold the application is very painful. With the galvano-cautery batteries in the market it is impossible to accurately graduate the temperature of the knife, and he showed a battery devised by himself for the purpose, which is so arranged that the zinc plates are suspended above the cups containing the carbons and fluid, and may be immersed to any extent by depressing with the foot a treadle on the outside of the box containing the battery. The amount of surface of the zinc plates exposed to the action of the acid determines the amount of electrical current and consequently the amount of heat in the loop of the knife.

The immediate result of the burn is the formation of an eschar and of a certain amount of acute inflammation which stand in a direct ratio to the extent of the burn, and therefore not too large an incision should be made at any one sitting. The ultimate result of the operation is the formation of bands of cicatricial tissue, which by its contraction as it becomes firm binds down the swellings and thus prevents the stenosis. In the same manner a curved galvano-cautery knife is used to cauterize the hypertrophied adenoid tissue in the vault of the pharynx above the soft palate. These operations, if proper care is exercised, are not at all dangerous or painful, and on that account are preferable to the application of chemical caustics, which, as a rule, give great pain to the patient and are in the end not as effective as the galvano-cautery. The author then went on to describe the methods employed by him for the removal of hypertrophies situated far back in the nasal cavity and of nasal polypi. For these operations he employs a wire snare invented by Dr. Jarvis, of New York, the steel wire loop of which is thrown around the hypertrophy or polypus, and by gradually reducing the size of the loop the tissue engaged by it is snared off. To prevent a return of polypi he advised the cauterization of the stumps with the galvano-cautery knife. This method of operating he found to be attended with very little if any pain and hemorrhage. Localized thickenings which are not infrequently found on the cartilaginous septum in old cases of nasal catarrh, and which produce partial nasal stenosis, may also be removed with the wire snare, but when these localized thickenings have become ossified, or when the obstruction in the nose is due to an exostosis of the bony septum, or to an enlargement of the turbinated bones, or finally to a bony spur from the palatine process, neither the galvano cautery nor the wire snare are of any avail, and the obstructions must be removed by drilling them away. For these operations dental engines have heretofore been used to hold and rapidly revolve the drills and burrs, just as the dentists use them for excavating decayed teeth. Within a short time, however, the author stated that he had substituted for the dental engine a small electric motor, invented by Mr. Griscom, and manufactured by the Electro Dynamic Company, of Philadelphia, to which the hand-piece carrying the drills and burrs is attached, either directly to the spindle of the motor, or by means of a short, flexible shaft. The speed of the drill can be regulated to a nicety by means of the automatic, adjustable battery, which belongs to the motor, from a few hundred to 16,000 revolutions per minute, and its power is equal if not greater than that of the dental engine. When used for operation the apparatus is suspended from the ceiling, which run over pulleys and carry counter weights so as to balance the motor in any position in mid-air, and in front of the patient, and to keep it in any position it may be placed in. This arrangement relieves the hand of all weight, and thus a much more delicate manipulation of the tool is possible than can be obtained with the dental engine, for in the latter instrument the hand has to support the weight of the hand-piece and flexible shaft or arm, and besides a good deal of the motion of the foot working the treadle of the fly-wheel is communicated to the hand, making it unsteady. The tools used are much the same as those employed by the dentist, except that when the bony obstructions are far back in the nasal cavity they should be longer in the shaft.

The operation is performed by riddling the bony obstructions with holes made with a cutting drill, and the substance between the holes is then broken down with a coarse burr, and, finally, the shreds of mucous membrane and spicules of bone are trimmed off with a pair of scissors. Usually but a very moderate amount of inflammation of the mucous membrane in the nose follows the operation, and the wound heals readily in a few days. As a rule, it is found more convenient for the operator to place the patient under the influence of ether, so that the involuntary struggles of the patient do not interfere with the operation; this is, however, not absolutely necessary, as the pain is not near as great as might be expected.

For the relief of the obstruction caused by deviation of the septum a variety of operations have been recommended, but the Doctor stated it as his opinion that the simplest, easiest to perform, and at the same time very satisfactory operation, is the following: With a strong pair of forceps which has inserted into one of its blades a number of knife blades, at right angles to the surface and arranged in the shape of a star, the septum is punched at its greatest curvature, by introducing the blade carrying the knives into the open nostril and the unarmed blade into the closed one, and then compressing the handles. The punch is then removed, and with a pair of forceps having flat blades the septum is forcibly straightened, which becomes possible since the triangular pieces produced by the cut made with the punch lap, and thus the distance from the base to the top of the septum becomes diminished. A wooden or ivory plug is then introduced in the formerly closed nostril, with a view to keep the septum in its new position, and is left there until the parts have sufficiently healed to remain straight without that support. This operation is also not very painful, and can readily be performed without ether.

For the removal of necrosed bone and for treating caries of bone in the nasal cavity, the

lecturer said he knew of no better means than the dental drill and burr attached to the electric motor, for the delicacy of movement of the instrument allows the hand at once to detect when the tool has penetrated the diseased structure and sound bone is reached.

Deep ulcerations of the mucous membrane in the nasal cavity, he finds, do not readily yield to the usual applications of chemical caustics, and, therefore, he treats them either with the galvano-cautery knife or the corundum cone mounted on a long shaft and revolving rapidly in the electric engine. When the ulcers are small the charring of the surface with the glowing platinum loop answers every purpose and is not near so painful as the application of solid nitrate of silver. If they are large, however, it seems best to freshen up the surface with the corundum cone, which, when rapidly revolving, enables the operator to remove all diseased tissue without injuring the healthy.

The paper closed with a few remarks on the medicinal after treatment of nasal catarrh, and was illustrated by the exhibition of the various instruments described.

Thursday evening a very handsome reception was given the delegates in the Oil Exchange, which is a very fine building. After the promenade concert dancing commenced at nine o'clock, and was continued until three in the morning.

FRIDAY MAY 12th.

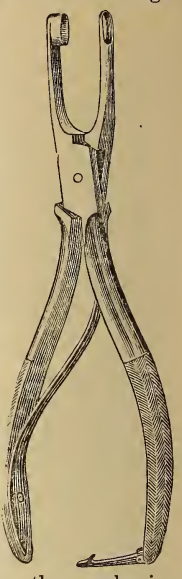
Society convened at 9 o'clock; prayer was offered by the Rev. F. H. Rowley. The Address in Obstetrics, by Dr. R. S. Sutton, was then read by Dr. Daly, of Pittsburg. It was a most interesting paper on Abdominal Surgery, in especial connection with ovariotomy, laparotomy, etc., and described the first operations of McDowell and Washington Atlee, and detailed the operations of Langenbeck, Shroeder, Martin, of Berlin, Nussbaum and others.

Dr. John B. Roberts, of Philadelphia, presented a paper entitled

Excision of Cartilage in Nasal Occlusion, due to Deviated Septum.

When the deviation is not very great, relief can sometimes be afforded by making a crucial or stellate incision in the cartilage, at the point of obstruction, and then pressing the weakened partition away from the side of the nostril. It can be kept in this position by a nasal bougie until the wound has cicatrized, if it tends to assume its original condition.

In very many cases, however, the most satisfactory treatment, because the most radical and expeditious, is to cut out a disk of cartilage at the point where deviation causes obstruction. This is best done by the nasal punch or cutting forceps here exhibited. The opening left between the nostrils is no objection to the procedure, because it does not weaken the support of the nasal cartilage materially, and is not small enough to produce whistling sounds during respiration. It is not visible unless the nasal cavities are examined carefully with light or with a speculum, hence it cannot be objectionable on cosmetic grounds. The fenestrated cutting forceps which I have had made are an improvement on others intended for the purpose, because the mucous membrane on both sides of the septum is more cleanly divided, the disk of cartilage is more likely to be removed by the forceps when they are withdrawn, and the instrument retains its keen edge longer. After an opening in the septum has thus been made, any remaining obstruction can usually be remedied by enlarging the orifice by cutting out additional pieces. When the forceps has been forcibly closed upon the divided part of the cartilaginous or bony septum, it should be rocked from side to side a little, to ensure entire division of the tissues.



There seems to be prevalent a traditional notion that the cartilaginous partition between the nostrils must not be perforated in the efforts to render patulous the occluded nostril. Hence patients with one nostril entirely stopped by deflection of the triangular cartilage are often told that nothing can be done to relieve the nasal voice and other symptoms of throat and nose disease due to the imperfect respiration. Sometimes attempts are made to relieve the trouble by dilating the narrowed orifice, or by paring away a portion of the surface of the cartilage. In the latter method caution is given, at least in some text-books, to avoid perforating the septum. This is a mistake.

Dr. William Varian, of Titusville, presented the following case of

Ovariotomy.

On the 16th of February, 1881, I called at the office of Dr. Charles B. Kibler, in Corry, when I chanced to meet Mrs. G., who, in the opinion of Dr. Kibler, was afflicted with a tumor of the left ovary. At Dr. Kibler's request, I made a hasty examination of the case. I found a firm, hard, inelastic tumor, as large as the womb at the fifth month of pregnancy, occupying the left hypogastrium and dipping deeply into the pelvis. It was smooth, had few perceptible irregularities of the surface, was movable, and free from pain and soreness when handled. Mrs. G. was 39 years of age, and her knowledge of the tumor extends over two years. A vaginal examination showed that the pelvis was well filled with the mass, and the womb, pushed somewhat to the right, was of an abnormal depth. I could detect no fluctuation, and the tumor, when moved, carried the uterus with it. The patient was in good health, well nourished, with an active circulation, and was remarkably free from either systemic or sympathetic disturbance. My examination was far from being a satisfactory one, owing to want of time. Mrs. G. was anxious not to lose a train nearly due, on which account I was obliged to dispense with the removal of a sufficient amount of her heavy winter clothing to enable me to have free access to and perfect command of the abdomen. In spite of this,

felt justified in diagnosing a uterine fibroid, and in advising non-recourse to operative procedure so long as her health remained good.

About eight months later, on the 10th of October, 1881, I again met Mrs. G. at Doctor K's office, when I found that a very marked change had taken place in her condition.

It appears that shortly after my examination in February, Mrs. G. had visited one of the Western States. While there, some time during the month of April, she met with a severe fall. Her feet slipping, she came down in a sitting posture with such violence that for twenty-four hours she was obliged to maintain a recumbent position. A moderate degree of lameness and soreness was the only apparent result of the accident for a period of two or three weeks, at the end of which time she noticed that she was beginning to perceptibly increase in size. This increase had steadily continued up to the time of our meeting, and was accompanied by soreness and discomfort, together with the sympathetic disturbances so common in these cases. She was now as large as a woman at the full time of pregnancy, and showed all the evidences of a rapid failure of the systemic powers.

I found the same firm, hard tumor in the left hypogastrium, apparently unchanged in size, which existed at the time of the previous examination. The rest of the abdomen was occupied by a large tumor, evidently containing several subdivisions, and yielding on palpation sensible, although somewhat indistinct, evidences of fluctuation. The two tumors could be completely separated, so that I was able to pass my hand between them to an extent only limited by my power of indenting the abdominal walls. Moving one growth did not appear to influence the other, unless made to impinge directly upon it. This examination was made under the same unfavorable circumstances as the first, but still I felt satisfied that there were two tumors coexistent in the case. The one probably ovarian and colloid, though possibly an elastic fibroid. The other a fibroid. I now suggested the removal of the ovarian tumor and with it the opposite ovary, expecting by thus producing an artificial menopause to completely control the further growth of the fibroid, and possibly to secure a decided reduction in its size. If I found the removal of the fibroid, with or without the uterus, indicated by the appearances presented after laparotomy, I would remove all the diseased organs.

Circumstances of a personal nature prevented my patient from resorting to an operation until four months had elapsed, when, on February 15th, of this year, I operated at the home of Mrs. G., near Columbus, Warren county, in the presence of the following gentlemen: Drs. Kibler, Elstone and B. H. Phelps, of Corry; Walling, of Columbus; J. T. Waid, of Spartansburgh; Sherwood, of Union; Whitney, of Lottsville, and Blaine, of Pleasantville. The patient at this time was very anæmic and prostrate. Her abdomen was enormously distended by a very large polycyst, easily diagnosed, the upper cyst giving free fluctuation, while the rest of the tumor gave that elastic semi-fluctuation so characteristic of cysts filled with semi-solid colloid material. A solid mass about the size of a pint bowl on the left upper corner was all that could now be traced of the fibroid, but this still retained all the characteristics of the original tumor. Every care had been taken to thoroughly prepare the patient and to render aseptic the room, as well as the patient herself, the surgeons present, the instruments, sponges and operator. As I anticipated a more than usually formidable operation, I had directed that the patient should be brought to a condition of incipient inebriation. By thus producing turgidity of the cerebral vessels I hoped to secure prolonged anæsthesia, with the least risk to my patient, and with a small expenditure of the anæsthetic.

I will not dwell upon the successive steps of the operation, as these vary only in minor details, and are too familiar to all present to be of special interest. Besides, each case furnishes its own laws and guides for its conduct; and my only endeavor is to accomplish the work which lies before me, after the abdominal section is made, with as much rapidity as is consistent with thoroughness, and to meet with prompt decision each emergency that arises, in the manner which at the time appears to be most likely to conduce to the ultimate safety of my patient. When permitted to exercise my preference, I now always drop the pedicle. But I use the clamp and other methods of treatment when they manifest special advantages in a case. So much by way of parenthesis.

I found but one tumor in this abdomen. This was a polycyst, of great size. All the cysts but one were filled with colloid material, which was almost solid in consistency. The exceptional cyst, a large one, contained the thick, dark-colored, viscid fluid so familiar to all ovariotomists, and so characteristic of a large number of ovarian cysts. On the left upper corner of the tumor was the firm, solid mass alluded to, which, when incised, presented all the sensible features of a genuine fibroid. This was an integral portion of the tumor. The pelvis was completely filled with organized fibrinous exudation, enveloping all its contents and rendering the developments of a pedicle to the tumor impossible. After an unsuccessful attempt to enucleate, I ligated the base of the tumor, and removed it. Its weight, with contents, was estimated at 45 lbs.

The patient was under chloroform about fifty minutes.

The after treatment was conducted by Drs. Kibler, of Corry, and Walling, of Columbus, and the skill, energy, and judgment displayed by these gentlemen merit a detailed report from day to day, but this is forbidden by the limits of this paper. A chart of pulse and temperature curves, furnished by Dr. Walling, is herewith submitted, by which we see that the highest range of the thermometer was 101°, which point was reached during the first twenty-four hours. During the second day 100° was the highest temperature attained. After this, 99½° was the greatest temperature, while the greater portion of the time, for many successive days, it did not exceed the normal. The pulse was quick throughout. During the first three days some bloody urine was drawn from the bladder, but this readily yielded

to the exhibition of the salicylate of soda. The patient suffered from urethritis and vaginitis, largely owing to bad nursing. The bowels acted normally, and the condition of the abdomen was all that could be wished, during the entire course of the case. At first the discharge was very free, and aseptic irrigation of the cavity of the abdomen was required several times a day. A sense of heat and soreness in the abdomen, which commenced on the fourth day, was promptly met, and as promptly subdued, by the ice bag, together with the exhibition per orem of quinia and opium. The silver sutures were withdrawn on the ninth day, at which time there was union of the entire wound, except where the drainage tube rested in the lower angle. On the 15th day all discharge had ceased and the drainage tube was removed. At this time the patient, her friends, and her physicians felt assured of a complete recovery. But, alas for human hopes; on the seventeenth day a violent attack of vomiting set in, which for twenty-four hours resisted all treatment, and produced an amount of prostration which in the end proved fatal. In spite of rectal alimentation, and every means which experience and ingenuity could suggest, the patient gradually sank away, and died on the twenty-first day. On the 8th of March I visited Columbus to perform another operation, and on my arrival was met with the sad intelligence of the death of Mrs. G., which occurred the evening of the seventh, just twenty-one days from the date of the operation.

It is due to Drs. Kibler and Walling to state that the patient was too poor to be able to provide herself with a trained and skillful nurse; and that she lay at a farm house, two miles from one of her doctors and six miles from the other. And during her entire confinement, the roads were in such condition, that whether the physician rode, drove, or walked to see his patient, he would be inspired with an ardent wish that he had selected some other method of locomotion. Under these circumstances, are we not justified in saying that neither patient nor doctor had a fair chance?

Although the case briefly reported above has an intrinsic interest of its own, yet I attach to it an added interest, because it appears to throw some light upon the possible reason of the rarity of the occurrence of ovarian fibroids, so far as their existence has been demonstrated by operation. That experienced and skillful ovariotomist, Dr. Wm. Goodell, states, in a clinical lecture recently reported, that the occurrence of fibroid tumors of the ovary is so rare as to have been denied by some writers. But that he had encountered three tumors of this nature, in his personal experience. I have myself removed one ovarian fibroid, and had I operated on this patient, in February, 1881, about the time I first saw her, I see no reason to disbelieve that I should have added one more fibroid to my list. For that this tumor was a fibroid, or at least what we call a fibroid, at that time, I see no reason to doubt. That the injury produced by the accident which occurred in April, or some other cause, had produced degeneration of the tumor, I also believe.

I ask, then: Is it not possible, and even probable, that this is a frequent termination of fibroid tumors of the ovary? And since recourse to operative interference is usually delayed until the patient's health begins to give way, may not this degeneration be the usual termination of this form of tumor? I well remember, in my earlier experience as an ovariotomist, how much I plumed myself on having successfully removed a colloid polycyst, which a year or more before had been pronounced a fibroid by a skillful and experienced ovariotomist.

Another question. Are colloid polycysts benign in their character, or do they possess the elements of malignancy? In other words, are they semi-malignant tumors whose incipient stage is represented by what we call a fibroid?

The hope of obtaining a reply to these questions is my only excuse for occupying your time and attention with a report of so common an occurrence as the removal of an ovarian cyst.

After which a paper on "The Use of Atropia," by Dr. E. Dyer, of Pittsburg, was read by title.

FRIDAY AFTERNOON.

Society convened at two o'clock.

Dr. Frances N. Baker then read a paper on

The Management of the Perineum During Labor.

Since the invitation to prepare a paper to be read before this Society came late, and the necessity for a prompt reply was urgent, I selected my subject somewhat hastily, and more with a view to what is to myself of interest and importance, than with a thought of what would either interest or instruct my audience.

Therefore, if any further apology than this seems needful for occupying the time of the Association with the consideration of so *trite* a theme, I will offer in my defence *the large number of lacerated perineums* that are constantly being found upon the gynæcological table.

I feel certain that either the *methods* which we have adopted for the protection of this important structure have been very defective, or that these same methods have been imperfectly *executed*, else we would not so constantly meet with the undeniable proofs of many disastrous failures.

This subject of "perineal preservation" (or support, as it is frequently termed) is entirely the outgrowth of civilization, for the ruder nations make no attempts whatever in this direction. And it would be a matter of much interest, and some profit, perhaps, could a tabular statement be obtained of the number of lacerations happening among a people who practice no manner or method of preservation, and then compare it with the number of tears occurring in the hands of those practicing the most active interference (even to the extent of unremitting support for ten or twelve consecutive hours).

Another item of not less interest would be a comparison of the *different* methods now in use for the avoidance of lacerations, with the percentage of failures belonging to each. But such information as this will scarcely ever be ascertainable.

Statistics upon perineal lacerations, outside of hospitals, are not very abundant. There seems to be great unwillingness on the part of the profession to acknowledge the occurring of this accident, unless it has happened at the hands of some other practitioner.

Again, in acknowledgments upon the subject a great difference exists in estimating the gravity of the lesion. What one observer estimates as a slight rent, another with higher ideals of professional success regards a tear of considerable moment. Then, too, we have no uniform standard of measurement, and the figures employed do not give a correct idea of the *extent* of the injury. The centimeter of one or the inch of another may mean much or little.

Since perineums are not all of the same dimension, we will arrive at a more accurate understanding of the condition, if we regard the whole perineum as the unit of measure, and then estimate the injury as fractional parts of the whole, rather than the length in inches or centimeters.

And, finally, one of the most vital causes of our incompleteness of information upon the number as well as extent of the injuries occurring to the perineum during labor is the failure of the physician to examine the patient after delivery, in order to ascertain just what the state of the parts may be. I speak advisedly, and of what I do know, when I say that, too often for her future comfort, he goes away without an idea of the mischief done, and she, so long as she has rectal and vesical control, believes that all is well, but finds, after she assumes her wonted duties, that she is *not* so strong as before her accouchement, and concludes that her debility and discomfort arise from the fact that she is an *American* woman, and that she has been unfitted for maternity by having had too much education. But, alas! for this pleasant little fiction, many women seek our private office and the treatment room of the hospital, who have neither college education nor perineums.

But before discussing the *methods* of preserving the perineum, a review of the *causes* that render some form of interference necessary will, perhaps, not be misdirected effort.

(1) In cases when the sacrum is too perpendicular, thus making the propelling force to act more in the direction of the perineum than in that of the outlet of the parturient canal.

(2) Where the pubic arch is too acute in its outline, thus preventing the head from filling the upper part of the arch, in which condition we have the force directed against the perineum with unusual energy. A narrow pubic arch is practically the same as a *long* symphysis pubis, and the head must go further down, in order that it may escape, than it would were the arch broad.

(3) A thickened state of the urethra and the subjacent parts has, curiously enough, been regarded as modifying the labor in the same manner as a narrow pubic arch. It certainly must do it only in a modified degree, if, indeed, it have a *noticeable* effect at all.

(4) Too little inclination of the pelvis, this anatomical peculiarity increases the risks to the soft parts, because of the liability to rapid labor.

(5) An excessive *width* of the perineum, the centre of it, consequently, receiving the force of the presenting part rather than directing it forward.

(6) Too *long* a perineum.

(7) *Rigidity* of the perineal tissues or of the vaginal orifice. The texture of the vaginal tissues, though thinner than the perineal, is at the same time less distensible. The *age* of the patient, too, if she be a primipara, may be calculated upon as predisposing to this rigidity, the condition of inelasticity being most common in aged primiparæ.

(8) If the tissues have been weakened by disease; also the presence of old cicatrices.

(9) Too much voluntary force exerted on the part of the patient.

(10) The use of ergot.

(11) The *sex* of child, too, may be regarded as a factor in calculating the probabilities of a laceration of the perineum; the birth of male children being attended with more danger to the soft parts of the mother, and especially if she be a primipara, because of the greater size of the male head. According to the observations of Clarke, of Dublin, the circumference of the male head exceeds the female by $\frac{3}{8}$ of an inch, and the length of the transverse diameter is $\frac{1}{8}$ of an inch longer. And that, as the order of labor rises in difficulty, the amount of male births rises in number." Then, under this same caption, I may include the commonly quoted cause, viz: "the disproportion between the size of fœtal head and the rima vulvæ," as well as the excessive length of the bis-acromial diameter, for the *head* may escape without producing a laceration, and the shoulder or elbow *produce* or *extend* one already commenced. Indeed, I think the shoulders, from their irregularity of contour, may, with propriety, be regarded as more formidable opponents to the integrity of the perineal tissues than the head itself. They have, however, the advantage of a previously dilated canal.

(12) Mal-presentation, as in face, when the mento-occipital diameter is made to extend the vulvar orifice at least $1\frac{3}{4}$ cm. more than in vertex presentations of anterior varieties.

(13) Mal-positions, as in posterior varieties of the vertex, where extension of the head occurs backward over the perineum. (Of course I allude to those cases where internal rotation forward has not occurred.)

(14) The awkward use of instruments. Awkward position of the patient, and the same may be added of the accoucheur. And lastly, but perhaps least cogently, is the idea in the mind of the physician (if he be young in practice), that "a certain number of perineums will have to be sacrificed anyhow."

Now, after even a brief consideration of the foregoing causes, some of which are entirely opposite in character, we may with safety conclude that no single line of treatment will be applicable to all cases, but that the "management" must be such as will meet the exigencies of each particular case under supervision.

And as the first pre-requisite of successful "preservation," I would consider a thorough knowledge of the anatomy of the female pelvis and its organs as most essential. And side by side with this topographical anatomy I would place a thorough and critical diagnostic examination.

The only safety is in *knowing*, and we can only know by an investigation of each and every case. We ought to know if the perineum be long or short, if there be much or little development of the parts that bound the vulvar orifice. If there be rigidity or relaxation. If tumefaction

or œdema exists. The *size* of the vaginal orifice. The persistence of the hymen. The condition of the vaginal walls, the presence of cicatricial tissues. If the bladder be distended or the rectum full. The condition of the pelvic walls and the dimensions of the pelvis as a whole, with the presentation and position of the fœtus. It seems to me the line of conduct is far plainer after coming into possession of these facts than before. In other words, the future of both patient and doctor is far safer.

And now, after being thus armed with a complete understanding of our case, we will often find that many of the so-called causes of laceration are removable, and that a portion of the remainder can be rendered innoxious.

(1) In this day and generation no perineum should be injured from the use of ergot. So long as the uterus is occupied by the fœtus, placenta, membranes, or even coagula, ergot is strongly counter indicated.

(2) The awkward position of the patient and physician is quite within control. In the second stage of labor the left lateral decubitus for the patient upon the right side of the couch, reckoning from the head of the same, makes her easy of access and places the attendant usually where he has the most ease of motion.

(3) Lacerations resulting from the *awkward* use of instruments are preventable in only one way, but the remedy is applicable to the physician and not to the patient.

(4) Too much voluntary force exerted by the patient is rarely a just excuse for a tear, since an anæsthetic has come to form an unforgetable article of the armamentarium. And while we can thus control voluntary effort with our anæsthetic, we have at the same time a powerful opponent to *rigidity* of tissue. And in this stage of labor I prefer chloroform to ether. I like, of course, to know that the condition of the heart and lungs is good, that no kidney trouble exists, and that there is no great probability of post-partum hemorrhage.

The condition of the rectum and bladder should *always* receive attention, no matter what the statement of the patient. A rectal enema of warm soap suds should be a matter of routine practice, if ever routine practice is admissible. The use of the flexible catheter during the second stage, even if not unduly prolonged, is good practice but not always easy. Of course this kind of management implies the early attention of the physician, and insures to the patient a great deal better service than many of them either appreciate or remunerate. But what shall we do to the *perineum?* Do *not* support it. Manipulations directed to the perineum destroy its integrity, and the best results follow support of the presenting part rather than of the perineum itself. With two fingers in the rectum you can have absolute control of the head after the mouth is accessible, and always should the presenting part be expelled in the *interval* of contractions. In many cases full control of the presenting part can be maintained by pressure upon it with the thumb and index finger, without resort to the rectal touch (which is always offensive to the patient). And at no time during the expulsion should we lose sight of the mechanical relations. If there be too much flexion favor the upward movement of the head toward the symphysis; this can best be accomplished from the rectum. Or if too early extension of the head occurs before relaxation be complete, favor flexion by pressure upon the presenting part backward toward the sacrum. "But if the axis of the fœtal cylinder is cutting the diameter of the vulvar circumference at a right angle then will the cylinder pass through the ring with least damage to its margins, and to push upward or backward would be to spoil the relations," and instead of giving intelligent assistance we would be substituting meddlesome stupidity. But what to do in those cases where a tear is inevitable? Then resort to the bilateral incision of the vulvar orifice. If the continuity of tissue must be destroyed control the locality, and as far as possible the extent, of the tear. These incisions should be made through the lateral margins of the orifice midway between the anterior and posterior commissures, and if the margins of the vaginal orifice form a constricting band over the presenting part, then the incisions should include the vaginal tissue also. Occasionally we need not include the vulvar tissue. A central tear of the perineum may commence as a tear of the vagina, but in the majority of cases the borders of both the vaginal and vulvar orifices need to be included in the tract of the bistoury or scissors whichever you may prefer to use.

The best made objections to these incisions is, that they do not always prevent a central tear, but if they save but fifty per cent. of the otherwise unavoidable central lacerations of the perineum they should not be abandoned. They are not painful if made during a contraction, and union without suture is more probable than in a central tear of the perineum, of the same length, because they can be made out of the reach of the action of the perineal muscles. And in conclusion, although the *title* of my paper does not *include* the treatment of lacerations when they have actually occurred, still I wish to record one more plea, and a positive one, too, in addition to the many already so well made, for the *immediate* repair of the injury. I quite fail to see why the repair is so often postponed. The benefits that accrue to the patient are incalculable; her consent, usually, easy to obtain; in fact, her morale at that time is very often better for the operation than at a subsequent period, while we have, naturally, all the attendant circumstances necessary for union (except the presence of the lochia). Then the sensibilities of the parts are reduced to a minimum, and an anæsthetic not always indispensable. So that we have an operation of comparative ease, which by delay is convertible into one both painful and tedious. So, in view of even these facts, I would *insist* that the *immediate repair* of lacerations of the perineum be regarded as part of the attending physician's *duty*, and the avoidance of it punishable, by at least, a *lower professional standing*.

Then followed a paper on "A Rare Case of Nervous Disease," by Dr. J. L. Stewart, of Erie, which was read by title. Then followed Dr. Levis' paper, by title, of which we give a short abstract.

The paper of Dr. R. J. Levis, on

Surgical Expedients in Emergencies,

presented some original resources in the absence of ordinary means and appliances.

The relief of an over-distended bladder he had effected by doubling a piece of common iron bell wire, and the blunt doubled end passed through the urethral tract, distending it and allowing the urine to pass between the wires.

A common rye straw, with its end wrapped with either thread or yarn, or tipped with sealing wax, or the stem of a common clay tobacco pipe, are efficient substitutes for the female catheter.

Venesection can be made easy and certain, with even a dull and blunt pocket knife, by first transfixing the vein with a fine sewing needle.

A number of ready and ingenious resources are given for the arrest of epistaxis and hemorrhage in general. A good tenaculum is extemporized from a fish hook tied to a pen-holder. A flannel bandage, cut bias, is sufficiently elastic to substitute the Esmarch bandage.

Expedients for ready fracture dressings are given, one of the best of which is the material of common palm leaf fans, split into fragments and bandaged around the limb. For a ready fixed dressing the ordinary sand-paper, softened in warm water, is recommended, the paper, sand and glue giving, when dry, the requisite stiffness and body to the splint.

Postural methods of treating fractures, as those in the vicinity of the joints, are referred to, and that of the clavicle by a brief recumbent position.

To open the mastoid cells in cases of abscess urgently threatening cerebral complication, he has effectively used a carpenter's gimlet.

Rectal injection by a hydrostatic column, with a long tube, is referred to; and also the distention of the lower bowels, in cases of invagination and impaction, by carbonic acid gas and water from the ordinary mineral water bottle, or the syphon attached to a rectal tube.

Stramonium is recommended for ready use in iritis and traumatic injuries of the eye when atropia is absent.

For simple, cheap and effective antiseptics, sulphurous acid, alcohol, whisky, and the salts of iron, copper and zinc, may well substitute carbolic acid.

After which Dr. William S. Roland, of York, read a paper on

Hæmaturia.

This term is of Greek origin, and means bloody urine, or voiding of blood by urine, and like other hemorrhages, it may be active or passive, and may come from the kidneys, ureters, bladder, prostate gland or urethra. There can be no difficulty in detecting blood when found in the urine, but the question of practical import is, to determine from whence does it come? and here, in this connection, I quote from an article by Dr. F. K. Bailey, found in the Philadelphia Medical and Surgical Reporter, Vol. xxvi, page 321, as follows: "Watson says 'Hæmaturia, strictly idiopathic, must be very rare.' Aitken only alluded to it incidentally in connection with albuminuria. Cullen remarks 'that neither he nor any of his friends had ever met with an instance.' Wood says 'It is by no means common, except as an attendant upon inflammation of some portion of the membrane lining the urinary passages, and even under these circumstances, is seldom so considerable, as to claim particular attention.' Eberle gives some excellent diagnostic circumstances which will guide us in giving locality to the origin of the blood voided from the bladder. Dunglison points out also the principal diagnostic marks to aid us in the study of cases which may come under our notice. Barclay, in his work on Diagnosis, specifies many points to enable us to determine the origin of the blood, but says 'These observations all tend to show that hæmaturia is almost constantly a symptom, though a casual one, of disease in some portions of the urinary apparatus.'" I further quote from Sir Henry Thompson's Lectures on Diseases of the Urinary Organs, as follows: "What is the source of it? Now, it is often not an easy thing to state at once what point of that long and complicated organic apparatus which commences in the Malpighian corpuscles, and ends at the external meatus, is the source of the blood in question, for sometimes it is exceedingly difficult to define its source. If the hæmaturia is the result of inflammation, there will be general fever denoting its presence; if produced by slow organic change, there will be history of failing health, and probably urine changed in quality, otherwise than by mere admixture of blood." Von. Ziemssen and other writers tell us that hæmaturia is sometimes the first symptom of renal cancer, that it may sometimes be developed without any preceding pain, and it is often impossible to make much out of this symptom, if it is quite isolated, though a renal hemorrhage arising without any external cause, and running its course without pain, is always to be looked upon with suspicion; another, perhaps more reliable, sign, is the discovery of a tumor, which makes the diagnosis passably clear. Taking the best medical authorities as our guide, we infer that primary cancer of the kidney is considered a rare affection, and when it does occur, is usually confined to one kidney, the right one being most frequently attacked; the kidney may not be necessarily much enlarged, and the disease may run its course without giving any very prominent symptoms on which to base a satisfactory diagnosis; pain in the region of the loins may sometimes be the first symptom, and that may not denote much significance. The most important symptoms to be considered are the renal tumor and the hæmaturia; the latter may be noticed at any early stage of the disease, but it is only the attending physician who has made himself familiar with the experience of others, and who has the opportunity of seeing the patient during the entire course of the disease, noting in time a tumor, and the successive appearance of hæmaturia, and all the other well marked symptoms that are daily brought under his notice, who will be prepared to make a more easy and reasonably correct diagnosis than one who is not familiar with, or who has only a partial knowledge of the case.

The above observations have been suggested by the following case, which came under my special notice and care:—

Dr. T. L. C., a retired physician, aged 74 years,

called on me at my office, in the latter part of March, 1881, and stated that he was troubled with hæmaturia, and in answer to my question, he said "it had troubled him more or less at various times for the preceding eighteen months, and perhaps longer, but the discharge was usually so slight as not to cause him any uneasiness, but lately the flow of blood was increasing, and beginning to alarm him, that he had taken quinine and tr. mur. iron, but the discharge still continued, though he really was not suffering from it, and thought he was gaining flesh. The Doctor, at that time, presented a fine personal appearance, bearing the impress of a well preserved gentleman; habits all good, and, temperate in all things, he looked the picture of perfect health and bodily strength, and he could not remember of ever having met with an injury at any time, nor could he assign any cause for his trouble. I suggested to him, to try fluid ext. of ergot; a few days afterwards he reported that the ergot acted like a charm in arresting the bloody discharges. About two weeks thereafter he again reported that the flow had returned, and was very bad. I then said to him that I thought the trouble was in the bladder, and advised him to continue the ergot and drink flaxseed or elm tea, which again had the effect of much diminishing, or nearly altogether arresting, the discharge. Some time afterwards, about the middle of May, the Doctor reported that the disease had again broken out, and was very much more obstinate and lasting longer than the other spells; that he thought the discharges of blood on some occasions averaged a pint and more a day. He now, for the first time, complained of pain, and a sensation of weight in the lumbar region, also pain and burning at the anterior extremity of the urethra. I desire here to state, that I never, for a day, lost sight of the case, from the time of his first reporting himself to me, but was in daily intercourse and consultation with him, and during all this time, of about seven weeks, he was treated with ergot, hamamelis, gallic acid, matico, acid. sulph., quinine, tr. mur. iron, etc., at such times and doses as the nature of the case seemed to indicate; he was also cupped and blistered over the lumbar region, and while he seemed to derive some benefit from the treatment, the discharge continued with short intervals, more or less, every day, and he was never entirely free from it for perhaps more than one or two days at any time.

On the 25th of May I informed the Doctor that I now had reasons for changing my opinion as to the location of his disease, and that I believed it was located in the right kidney, that it was alarming in its nature, but not necessarily immediately fatal, and suggested a consultation, to which he readily assented, and said we would go to Philadelphia; accordingly on the next day we went to Philadelphia and saw Dr. J. H. Brinton; the Doctor made a thorough and searching examination, but failed to discover any signs of calculi, and said he did not believe there was any stone there. I then said to Dr. Brinton that the trouble, in my opinion, was not in the bladder, but was in the right kidney; he seemed to think, and so expressed himself, that possibly I might be right, and said he had no suggestions to make regarding treatment, other than what I was doing. On the 31st of May I wrote the following in a letter to Dr. Brinton: "Will you confidentially give me your opinion as to the character of our friend's disease; I have partly formed an opinion, but dread to name it. I hope I am wrong, and will most gladly accept any other name; there has at no time been such prominent symptoms as to lead me to think of diagnosing Bright's disease or calculi, but I fear cancer of the right kidney." To which the Doctor, the next day, replied as follows: "I am afraid your diagnosis is correct; our friend is evidently suffering from hæmaturia, and his face has a dreadfully cachectic look; of course we cannot tell the exact nature of his trouble. There are hardly the symptoms of renal calculus, so that we must look further. I fear that he will not improve, and I should doubt any therapeutic agent doing him much good."

During the month of June there was at no time any marked improvement in the condition of the patient; when there was a diminution in the blood discharges, there seemed to be an increase in the pain, and at times very severe, involving the loins, hip, thigh and leg of right side; there was generally obstinate constipation with occasional diarrhœa. On the 27th of May and 22d of June he went to Atlantic City, in hope of being benefited by the change, but in each instance, after a few days' trial, he was obliged to return home, always feeling worse for the trip.

About the middle of July Dr. A. R. Blair, of York, was called into the case, and he agreed with me fully in my diagnosis. The same treatment was continued, but there was no change for the better; the pains were constant and severe, and the desire to pass urine was frequent and painful; sometimes the flow would suddenly stop, and after numerous hot water applications over the bladder, large clots of blood would be forced out, and then, to afford relief to his sufferings, large doses of opium were freely administered. Œdema in the right limb now set in, and there was also evidently a tumor in the region of the right kidney, which had been previously noticed. On the 27th of August the right thigh and leg measured in circumference two and one-half inches more than those of the left side, and on the 30th the dimensions had increased to four and one half inches, and he now complained, in addition to his other painful afflictions, of an agonizing pain, locating it about the last lumbar vertebra, over which, after tr. iodine and other local applications, there was applied a compress, wet with a solution of atropia, and covered with oil silk, which he thought afforded some temporary relief. From this time on to about the middle of September, the blood discharges diminished, the pains were not so severe, and the œdema was getting less; his rest was not so often disturbed, and the anodyne doses were reduced; but he would take very little nourishment, and was all the time bed-fast, so that we did not feel much encouraged in hope of any permanent improvement. On the 20th of September the volcano again broke forth in great fury. The limbs of the lower extremity, left side, now commenced to fill, and soon were as full as the right ones had been; the discharges of blood were large and frequent, difficult and painful, the pains in the

back and along the course of the ureters and running down both limbs were alarmingly increased. The quinine was continued and stimulants at regular intervals were allowed. Opium was freely administered. This plan of treatment seemed now to afford the only relief for his intense sufferings. During part of intervening period up to October 21st he seemed at times to suffer less pain, the œdema was less, being about the same in both limbs, which had been kept down with bandages. From this time on there was no appetite, memory tardy, mind occasionally for a short time wandering, and when asked what he was talking about said they were only dreams; he was nervous and weak.

October 22d. Is getting weaker all the time, but rests quietly, except when obliged to micturate, which is now very frequent and painful; the desire coming on almost every half-hour; when not under the influence of the opiates, he is not disposed to talk, but readily answers all questions, when roused up; pulse running high and respiration is being interfered with; tumor in right side increasing, and discharges chiefly blood. Authorities tell us "In malignant renal tumor, blood may be found in large quantity at times; the rapidity of growth, and the size attained, are marked characteristics of the disease."

From the 23d to the 28th of October there was a continuation and aggravation of all the symptoms, until he was relieved of his sufferings, by death, which occcurred on the 28th, at 11 A. M. The following is the analysis of the urine, examined June 23d, 1881:—

Physical and chemical characters.—Color and appearance smoky; odor normal; reaction. slightly acid; sp. gravity, 1.023; albumen; nitric acid and heat tests, separately and combined, give about ¼ albumen; ring tests give albumen. Sugar, none detected; deposit; after standing 12 hours, there is a dark red deposit, not very abundant.

Microscopical appearance.—Crystals, none.

Anatomical elements.—Field full of red globules; very abundant; also some white globules.

Casts.—No casts found in 3 slides examined; epithelial cells from bladder, ureter and kidney.

Examined August 19th, 1881.

Appearance smoky; reaction acid; sp. gravity 1.018; albumen test gives about 1-5 bulk; sugar none; deposit red, after standing over night.

Microscopic appearance.—A few phosphates and oxalates; blood; some red corpuscles, large number of white or pus corpuscles; casts none; epithelial cells rather abundant.

During the entire course of the disease, continuing about seven months from the date when I was first consulted, the patient, at all times, except when suffering pain, was calm and resigned; and as to his condition, he did not at any time speak of, complain, or refer to the nature of his affliction.

There, unfortunately, was no autopsy, and hence the true character of the disease must remain obscure forever; nevertheless, my diagnosis shall remain unchanged.

Dr. Henry H. Smith, of Philadelphia, offered the following resolutions:—

Resolved, That this Society *re-affirms* its adherence to the code of ethics as adopted by the American Medical Association.

Resolved, That the delegates of this Society to the meeting of the American Medical Association in 1882, be instructed to enter an early protest against the admission to the Association of the *delegates* of any State or other Society that objects to and does not observe said code of ethics in all its branches. This resolution was seconded by Dr. John L. Atlee, of Lancaster, who said he would have gone to California to second the resolution of Dr. Smith.

Similar resolutions unanimously passed by the Philadelphia County Medical Society were read, as referred to the State Medical Society. Drs. E. P. Allen, Bradford Co., H. H. Smith, A. Hewson, Philadelphia, Jackson, of West Chester, Varian, of Titusville, and others, spoke concerning Dr. Smith's resolution, which was unanimously adopted.

The Society then finally adjourned, loud in their expressions of praise of the hospitality of the profession and citizens of Titusville. The delegates were all entertained with the most sumptuous hospitality in private families, while general receptions were given by Drs. Varian and Moody (who were untiring in their efforts to entertain), by the Mayor of Titusville and many others. The Society meets next year at Norristown.

Annual Meeting of the Sanitary Council of the Mississippi Valley.

The annual meeting of this Council was held in Cairo, Illinois, April 19th and 20th, 1882. The president, Dr. J. J. Speed, of Louisville, Ky., was in the chair, and Dr. John H. Rauch, of the Illinois Board of Health, acted as Secretary.

The New Orleans Medical and Surgical Association was admitted a member of the Association, and Dr. L. F. Salomon took his seat as its accredited representative. It was decided that after this year the fee of membership should be five dollars per year from all organizations belonging to the Council. The committee on river inspection by the National Board of Health reported as follows:—

Mr. President and Gentlemen:—The committee to whom was referred resolutions adopted by the State Board of Health, resolutions adopted by the Michigan Board of Health, executive correspondence relative to Mississippi quarantine stations; presented by Dr. Salomon, of New Orleans, resolutions presented by Dr. G. B. Thornton, of Memphis, and a communication from the National Board of Health, relative to river inspection service, respectfully return above mentioned papers, and recommend the adoption of preambles and resolutions as follows:

WHEREAS, The prevention of the introduction of yellow fever into the United States is a subject of national importance, and

WHEREAS, We believe that there is no safety if an infected vessel is allowed to enter the Mississippi river;

Resolved, That in the opinion of this council it is proper for the Louisiana Board of Health to ask, and it is the duty of the National Board of

Health to continue to give, aid in the prevention of the introduction of yellow fever into the Mississippi valley;

Resolved, That it is the duty of the National Board of Health to aid in the prevention of the introduction of yellow fever and to give accurate information to all States interested in the sanitary condition of the Mississippi valley.

1. An inspector of the National Board of Health should be placed at Eadsport, to act conjointly with the officer of the State Board of Health in securing the exclusion of infected vessels from the Mississippi river, and in notifying such vessels that they must be thoroughly disinfected. (2) That a representative of the National Board of Health shall be stationed at the Mississippi river quarantine stations. (3) That it is the duty of all health authorities in the Gulf States, promptly to communicate to the National Board of Health any and all possible information relative to the occurrence of yellow fever, or of a case which may be suspected to be yellow fever, and in every possible way to aid the National Board of Health to perform its duty in giving accurate information for the guidance of State and other Boards of Health throughout this country.

Resolved, That this Council, duly appreciating the utility of an efficient inspection service during the summer months, for the Mississippi river, and for railroads having their terminus on the Gulf coast, and also the efficiency and moral effect of such service as was maintained by the National Board of Health during the past three summers, do now respectfully request the National Board of Health to reëstablish that inspection service in the Mississippi river for the approaching summer—that is to say, until the middle of October.

Resolved, That the National Board of Health be requested to place on duty at New Orleans, and such other southern ports as may be deemed necessary, an inspector or inspectors, whose duties shall be to supervise the shipment, by river or rail, of all goods, merchandise, baggage, etc., and to inspect persons when necessary, and to advise by telegram, the secretary of each Board of Health interested in the matter, whenever such goods or persons are believed to be infected, or in anywise dangerous to the public health.

Resolved, That the secretary of this Council be instructed to transmit to the Secretary of the National Board of Health a list of the health organizations forming this Council.

WHEREAS, Measures for the prevention of the introduction of disease from foreign countries into the United States are of national importance, affecting not only the seaboard and Gulf states, but also the interior, as evidenced a few years ago by the widespread disaster from yellow fever, and recently by the widespread diffusion of smallpox, and,

WHEREAS, Hitherto the efforts of State and local health organizations have proved inadequate in giving needed protection;

Resolved, That in the judgment of this Council such measures shall be taken by the government as will most effectually prevent the introduction of contagious and infectious diseases into the United States.

Resolved, That the work of the National Board of Health and its objects meet the cordial approval of this Council, and this Council respectfully and urgently requests the Congress of the United States to make the necessary appropriation to enable the National Board of Health to continue its work.

Committee: HENRY B. BAKER, DAVID P. HADDEN, GUSTAVUS DEVRON.

A special committee was appointed, to which was referred certain papers and resolutions relative to inspecting and quarantining of immigrants, to prevent the introduction and spread of smallpox. This committee submitted a report recommending that immigrant inspection and means for protection against the smallpox for the year 1882 should be commenced May 1st, and that all the State and local sanitary organizations interested should unite, and should coöperate with the National Board of Health in order to accomplish the objects desired.

It was also resolved that this Council deems it important that clothing and baggage on board vessels and cars coming from places infected with smallpox should be disinfected, even though, by reason of vaccination, no person on board such vessels or cars contract the disease.

Upon motion of Dr. R. W. Mitchell, a committee was directed to be appointed, which shall inquire into what effect, if any, the recent inundation of the Mississippi river may have on the general healthfulness of the people of the Mississippi valley, and report at next annual meeting.

Drs. Thornton, Stephens, Solomon and Farquharson were appointed as such committee.

The following officers were then elected for the ensuing year: President, Dr. G. Devron, of New Orleans; Vice President, Dr. D. B. Hillis, of Iowa; Secretary and Treasurer, Dr. J. H. Rauch, of Illinois. The Executive Committee of the Council was requested to call a meeting at an early date next year, if deemed necessary. After an address by the President on "The Necessity of National Control of the Prevention of the Introduction of Yellow Fever and Smallpox into the United States," the Council adjourned.

MARRIAGES.

ELDRIDGE—HOUGH.—May 10th, in Elizabeth, N. J., by the Rev. L. P. Hornberger, of Philadelphia, Mr. John D. Eldridge, and Miss Ella L., daughter of Dr. T. L. Hough, all of Elizabeth, N. J.

NEVILLE—BROWN.—Wednesday evening, March 22d, 1882, at Chambers Presbyterian Church, by Rev. J. M. P. Otts, W. H. H. Neville, M.D. and Miss Lida T., daughter of E. D. Brown, all of Philadelphia.

PETTIGREW—HUTCHISON.—At the residence of the bride, May 10th, by the Rev. W. G. Reed, Samuel Pettigrew, M.D., of Du Bois Pa., and Emma Louise Hutchison, of Springdale Pa.

DEATHS.

BROCK.—At Morgantown, West Virginia, April 24th 1882, Hugh W. Brock, M.D., Professor in West Virginia University.

GARRISH.—On Tuesday, April 25th, J. Pool Garrish, Jr., M.D., at his residence, No. 66 West 46th Street, New York.

GILBERT.—At Gettysburg Pa., April 20th, 1882, of consumption, Dr. John E. Gilbert, aged 29 years and 9 months.

HOFFMAN.—At Reading, Pa., on April 30th, Dr. James M. Hoffman.

WHOLE No. 1317.] MAY 27, 1882. [VOL. XLVI, No. 21.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

A CLINICAL LECTURE ON IDIOCY AND IMBECILITY.

Joint meeting of the Medical Societies of Delaware and Chester Counties,

BY ISAAC N. KERLIN, M.D.,

Medical Superintendent of the Pennsylvania Institution for Feeble-minded Children.

(*Concluded from page* 537).

The literature of microcephalic idiocy is very voluminous; phrenologists and psychologists have made the head measurements and mind capacities of these malformed creatures the ground for wordy strife, from which they have carried away nothing, and have surely left no advantage to the innocent objects of their con troversies. It has certainly been demonstrated that the size of the brain is not an essential measure of intellectual ability; a genetous imbecile's brain has weighed 70½ oz. or 10 oz. heavier than Cuvier's; while another weighed 63 oz. 4 drachms, which is heavier than that of Dr. Abercrombie. On the other side, we have the whole ancient Peruvian race, with its wonderful metallurgical, engineering, weaving and agricultural skill, a microcephalous race. Hence, we should not be surprised at the capacity of some of our microcephalic idiots, and the want of it among many of those whose heads are normal, or, indeed, large in size.

Of microcephalic idiots we show you this typical case: according to Topinard, the greatest circumference of a true microcephal is not over 13 inches; 7 inches for microcephals, and from 17 in to 18 in. 10 lines, for semi-microcephals.

"It is to be fairly assumed," Dr. Ireland very properly remarks, "that below 17 inches in circumference, the manifestations of intellectual power would be feeble," and he gives any measurement below it as microcephalic. Indeed, he has measured no Scotch idiots below 18 inches.*

Most of our small-headed children are alert, interested, and active creatures, due probably to the large development of the cerebellar and spinal nervous tracts. They have been likened to apes, and their condition has been attributed, by a certain class of thinkers, to atavism, or the reappearance in low forms of humanity, of our simian ancestry. Gratiolet carefully took this up, in 1860, as a matter of study, and shows, from morphological examinations, that the microcephalic brain is a human brain, developing radically different from that of the ape; he proves that microcephaly precedes birth, and that the general form of the brain and its principal fissures correspond with that of the human infant in the fifth month of intra-uterine development.

It is somewhat common to find a family of microcephales; we have in our population of 350 three representatives of families containing more than the single microcephal. In one of these there have been five microcephalic births. The mother is almost a half-witted woman, with a very long and narrow head, small, but not microcephalic.

The three Ceratti brothers, whose interesting lives are written very fully, are three of seven, of a semi-idiotic parentage. The neighbors did not ascribe the peculiar idiocy of the children to

*Ireland on Idiocy, p. 79.

Providence, as is the common habit, but somewhat more sensibly (!) to the presence of a monkey, which Mr. Ceratti persisted in keeping in the family.

I will call your notice to three cases of *Idio imbecility*, ranking in mental condition, as the name would imply, between idiot and imbecile. Ella A. and Lilian C., present—in their facial appearance, dwarfed bodies, deformed heads, narrow buccal arches, imperfect teeth, etc.—the lowness of their grade. I need only add that their intelligence is rudimental. They are extremely sensitive, shy children, and are susceptible of considerable improvement. They are several removes from the hopelessness of profound idiocy.

I regretfully put Johnnie H. in the same category; a child taken into our care at five years of age; so pretty, perfectly formed, and exact in his movements, that all visitors exclaimed at the cruelty of "having such a child in such an institution;" but his mental outfit was limited and deranged; at home he had been kept tied, for fear he would fall from the window-sills, the boy having absolutely *no knowledge of height;* the cerebral centre ruling this dimension was educated at last, or another acted vicariously; whatever the physiological transposition, height seemed to be a devil which, once admitted to his comprehension, "brought other seven devils with it."

The sweet-faced boy bent his new acquirement to the injury of his playfellows, whom he maliciously pushed from ladders, or from window-sills, or from the top of embankments, with a persistency and devilishness in the act, and yet with an innocency of after manner, that beggars description. The various freaks of this propensity have been protean as the forms of epilepsy itself, and cannot be detailed; a few months ago it was noticed that John had frequent falls; they were instantaneous, like the tricks of a clown, and the composure and immediacy with which he regained his chair, and the willful smile at the nearest, impressed the attendant that this was another of his freaks; but a special and more intelligent watch being kept, of these phenomena, discovers the pallor, the momentary unconsciousness, the staring pupils, the slight spasm of the facial muscles—indications of an epileptic change which has gradually but surely developed through the five years of this boy's life in our institution.

We are helped in our understanding and treatment of Johnnie's case, as in that of Mamie, when regarding these eccentric propensities of idiocy as the irregular manifestations of that *epileptic change* which Nothnagle has described as the precursor of, and underlying, all epileptic states. These three are all genetous idiots, with interesting pre-natal histories. Ella would be produced, in the ethnological classification of idiocy, as having been arrested in her development at the period corresponding with the evolution of the Negro; but her mother insists upon it that the cause of her very peculiar appearance is the persistent and curious attention she gave, while enciente, to Barnum's "What Is It?"

We now pass to the representatives of the lowest grade of imbecility. Of these nine children, it is difficult to select the type of the class, notorious as all imbeciles are, especially of this grade, for their strong individuality.

T. T. aged 12, a genetous microcephalic paralytic imbecile, of low grade. Articulation quite imperfect; senses of sight and hearing good; hand well formed; imitation above the grade in which I now place him; cruel in his disposition, showing discrimination, analysis and candor, when he says "he likes to wear heavy boots—good to kick boys with." He is the better of two similarly malformed and imbecile brothers now living. Two deceased brothers were also microcephalic, resembling, markedly, this case. Nothing more intelligible is furnished by our correspondent, as to causation, than that "these three brothers were all born so."

Willie and Edith represent a special group found in all institutions, and which, in the ethnologic classification referred to, has been termed "Mongolian," sometimes "Kalmuck." The outer canthus is usually directed upward, the hair is sparse on the forehead, the occiput is flattened, the ears often incomplete, the tongue rugose, from hypertrophy of the papillæ. Dr. Wilbur has stated that about 6 per centum of the admissions to institutions are cases of this kind; they are found in every State and country; they present striking resemblances to each other, wherever found and from whatever origin. They are all of happy dispositions, often witty and grotesque; rarely live to twenty, and generally die of phthisis. So corresponding are the peculiarities of these children, that you will not fail to notice in another group before you Samuel, whose incomplete ears and rugose tongue will establish the truth of your selection.

These "Mongolians" are all genetous idiots and imbeciles. I have never known any of them to advance to the highest grade of imbeciles, even with the best training and care. They are

usually found a degree only above idiocy, in the lower ranks of imbecility.

Annie O., Johnnie H., Annie J. and Willie G. represent an interesting class of mutes, numbers of whom, with perfect hearing, ready appreciation of language, and often dexterous finger and hand capacity, find their way into this Institution, where, through the special training in articulation, and under the inspiring effect of concert recitation and song, they come to the partial possession of speech; they rarely become perfect in speech; according as the capacity is gradually developed, they are carried forward into the higher ranks of intelligence, and become our most interesting children. The idiocy or imbecility displayed by them is, as often as not, the effect of their isolation; the brighter children of a family outgrow them; they betake themselves to solitary lives and belittling occupations, until the range of their intelligence becomes very limited. They are the Kaspar Hausers of our community. Laura Bridgeman, but for the indomitable faith and effort of Dr. Howe, who recognized her necessities as early as her sixth year, would have sunk into the lower life of an imbecile.

These four are all interesting in their way, but I will take two from the middle grade of imbecility, Georgie and Walter, as illustrating the great advance made by honest work for this class of weak-minded children.

Walter, aged 21. We know little of his antecedents. There was a half aunt, on the father's side, who had convulsions at ten years of age, and who was afterward idiotic. The father was grossly intemperate, abused his wife, and separated from her before the birth of this boy. Scrofula and consumption are hereditary diseases in the father's family. The father died of phthisis, at 43 years of age; the mother of the same, at 35 years. The latter was of good family, but said to be of not strong intelligence. At three years of age Walter had an attack of cerebro-spinal meningitis, in the convalescence from which he was paralyzed in his lower extremities, lost his speech and hearing, and had numerous convulsions. He was admitted to this Institution when 10 years old. It was said of him, by a neighbor, "that he had come to the partial use of his speech, had committed the alphabet, had drawn on his slate, showing some talent for it, and had committed to memory short pieces; but from this he had relapsed, by the unavoidable neglect of his unfortunate mother, and because of his own stubborn tendency to solitude, which led him to the woodshed, where, alone and in silence, he could indulge his liking for whittling innumerable little wagons, of the most persistent pattern. His exercise of speech became thus more and more limited, and his already dull hearing became more dull, from disuse, and partly from an increasing morbid indifference to voices, so that when admitted to this Institution he was believed to be entirely deaf, watching the lips, and reading them to a slight degree, and answering questions only by the repetition of his own name imperfectly spoken.

It was a month before we realized that the boy was imposing on us, in the avoidance of any intellectual attention to sounds; the impediment to hearing, though serious, was made absolute by his lack of volition, to exercise what little remained. An absolute, almost harsh, treatment and course of training was at once commenced, and ere many months he became interested in his own accomplishments, learned rapidly to read and write, and was brought up from the condition of idiocy from deprivation into which he had well nigh settled. He has developed an aptitude for painting, and does much of the neater and precise kinds of wall painting which you may see through the house. His speech is comprehensive of all the business and details that enter into his daily life; his hearing is dull, but he exercises a tremendous volition, and receives more by his ears than he ever could from the most adroit lip reading.

Of middle grades of imbecility I present these as illustrations: Five hydrocephalic imbeciles; two epileptic paralytics; three choreic; two in whom there are evidences of congenital syphilis, and two cases of imbecility uncomplicated by accessory disease. Perhaps among these hydrocephalics there may be a case of hypertrophy of the brain; if there is, we are unable to diagnose it. But, as already referred to, there are cases on record of idiot brains weighing seventy-two ounces. Among these Websterian heads there are no Websters, for the brain, if brain, is of a low organization. In about fifty autopsies which we have made in this Institution we have never discovered a hypertrophied brain. The fluid contents have frequently surprised us; and from what we have hitherto seen, we can imagine that the five cases before you may average one pint each in their ventricles. Perhaps in Willie's the lateral ventricles, corpora striata, etc., are absent, the interior medulla and gray ganglia, dissolved out, as it were, leaving the brain a mere sac; but the gray and white substance are so harmoniously balanced that we have surprising degrees of intellectuality left. Indeed,

these poor fellows stand well among their mates for actual attainments and hopeful possibilities.

The choreics of our family are an interesting, energetic, industrious group, battling courageously with the heavy odds against them. I am surprised that in Dr. Ireland's pathological classification he has not distinguished a class as *choreic idiots*, presenting, as they do, some very marked characteristics.

They resemble one another in their mental and moral natures as closely as the so-called Mongolians resemble each other physically. They are all willing workers, fond of notice, and strongly attached to persons. They are more adherent in their natures, to person and place, than is the case usually with imbeciles. An imbecile, pur sang., finds in the last friend its best friend, and home is a relative consideration only.

Wilson is additionally interesting as presenting the ataxia, mis-shapen skull, dirty skin, and other suggestions of syphilitic taint.

Sarah, from the same middle grade of imbeciles, but not choreic, presents, in addition to the congenital taint of the other, well marked Hutchinson teeth. Syphilis as an element in the production of idiocy is difficult to prove, because of a stolid reticence on this disagreeable subject. It is acknowledged in only about two per centum of the families interrogated by us.

I finish this description of the middle grade imbecile by introducing two lads, in whom there are no complications such as exist in all the others.

H. is the illegitimate progeny of a feeble-minded woman, sired by a vicious, half criminal man, who has always lived in the almshouse of his county, on which he is said to have bestowed some six or eight pauper half-wits during the last twenty years. H. unites in himself some strikingly opposite attributes; he is affectionate, stealthy, cruel, bold, cowardly, industrious, tricky and sensitive. He has been cured of kleptomania several times! he has eloped under a fictitious name, and has been shut up in a Western refuge for many months, returning penitent to us, and eloping again. He prefers now to be fastened nightly to his bedstead, that the impulse of his Arab nature shall not overcome him. His mentality cannot grasp the simplest rudiments of school learning, but he is deft with his hands, and can gracefully handle the oven peel, mould the loaves of bread, and will become, I hope, an accomplished baker. His criminal ancestry might be supposed to outcrop physically in his hang-dog expression when admitted, his short bull-like neck, coarse, staring hair, and heavy movements. You will note the peculiar ears, a veritable "ear mark," by which he was reported to us as being in Pittsburg, under arrest.

We will present, as illustrative of the highest order or grade of imbecile children, eight individuals, some of them growing into adult life.

The unfairness of denominating these by the generic title of *idiocy*, a word that has become obnoxious in all modern language, will be realized at once by every sensitive man present.

The mental deficiency or deviation is often so slight, or the imperfection is found in such a limited range, perhaps involving only the power to form a judgment of values, or a judgment of social proprieties, or a judgment of moral risks, or a judgment of the prevalent wickedness outside of asylums, that it may seem strange that any of these, and especially of the next class we shall present, should be under the care of an institution of this character.

Eugene V. and Ida H. Both of these developed a precocious and apparently healthy infancy; both gave early evidences of highly neurotic conditions, which advanced to the degree of epilepsy in the lad, and which in the girl displayed itself in maniacal passion to bite and injure those about her. In my opinion, the "propensity" of the girl was as much an epilepsy as was the well-defined convulsion of the boy. The propensity of the latter was to rush into a violent passion, terminating in an epileptic explosion; of the other, any excitement of the feelings, whether painful or pleasurable, was followed by pallor of the face, slight twitching of the eyelids, or alæ, and an instantaneous leap toward child, friend, or mother, whom bitten, the paroxysm had passed. The lad passed through the best medical treatment at his home; was thoroughly bromidized, and circumcised; but the disease persisted, and the precocious intelligence of his earlier childhood was rapidly being effaced. The change to an institution, with its methods in eating, sleeping, and balanced occupation of mind and body, was followed by an immediate arrest of the disease, and the interesting fellow is tediously finding his way back through forgotten things, and gaining, I hope, new notions of manliness and self control, that shall preserve him from a sad future.

Ida is not so hopeful, but yet has very greatly improved, and rarely has her "convulsion."

I have not time to more than hint to you that the epilepsy of our imbecile children is often superficial; an attack is easily induced; a threatened attack is as readily repulsed by a strong

psychic impression; as, for example: epileptic children have yielded for years to the prohibition, "never to have a convulsion in 'praise meeting,' 'dance hall,'" or other assembly room, from which, if interdicted, they would lose many good times; on the other hand, a pencil grasped by the fingers of an epileptic child was found to be the factor of his school-room convulsions, displaying how delicate was the reflex irritability, which could not tolerate a certain continuous cramping or tension of the muscles and nerves of the fingers, without general spasm. An alarm of fire produced a convulsion in a nervous boy who had never been known to be so affected; while the promise of a carriage drive, exploded another lad in the same way. The distention of the great intestine by an enema, in a case familiar enough with the remedy not to fear it, was the event of one of the most alarming convulsions I ever saw; the lad was believed to be non-epileptic. The administration of chloroform to a girl whom we were preparing for the removal of a supernumerary toe was attended with a well marked eclampsic or epileptic fit. She had not had a convulsion since her infancy.

Arthur H., Harry S. These are typical cases of idiocy from deprivation, who, under the advantages of educational influences specially adapted to the protean forms of this infirmity, come to the first rank, many to become self supporting, under kindly guidance, but who, left to themselves, sink lower in their enforced isolation. Like Walter, there is in both these a double deafness, first of audition, and secondarily of attention. The degree to which this has gone in Arthur would seem to have placed him outside the relief of even our schools, but beginning as a little fellow, with the hand and speech training of our Kindergarten department, he has slowly learned to read and write; his fingers were early cultivated with the paper plaiting, crocheting and dainty play-work of the desk; grown, he is prepared for the shoe-shop, where, I am assured, he will make a fair mechanic.

Harry comes from a stock somewhat noted for sluggishness of speech in early childhood. His father could not speak intelligibly until seven years of age, and his articulation is still quite imperfect. Others on the father's side were very late in learning to talk. The mother has hereditary scrofula, and is not well balanced. There are four other children, all of whom are as defective, or more so than Harry. Troubled with the phonetics of the village, these children and their parents have constructed a convenient language of their own, which prudently omits the several vowels and consonants which are at all embarrassing, and yet supplies their local needs.

To nip in its bud this "Kingdom of its own," the Directors of the Poor concluded to strike at its vernacular, and removed the head centre, this oldest boy, whose mischievous ability to organize an idiom we are requested to abolish. But I greatly fear that Harry will retain his congenital nervous impairment, whatever that may be, which interferes with the organic utterance of spoken language, that is of the common language outside his own family. A few of his familiar words are—

Cigar as kēkä; Turkey as kertû; Sleigh as clāy; Shafts as clăs; Beads as vēes; Rooster as voofer; Butter as boohoo; Self as cōp; One quart of milk as oo coo bĭz.

Some years ago, a defective lad gave us a somewhat similarly definite vocabulary, which he had enforced upon his family and friends The following are illustrations:—

Bee wee meant little, small or few; Hawdey meant up, out, away; Bobby meant dog; Dindey meant car or cars; Dawday meant Sunday or God's day; Daddy beau meant a nurse; Gongy meant dirty, ugly; Gongy bomey meant dirty, ugly (more emphatic than gongy); Houngy meant home; Hou-day meant this day; My meant I, me, my; Own hoo meant sugar; Pee bay meant bread; Pee pay meant papa; Tee haw meant cold water; Tingting day meant Christmas day; Tondy meant a carriage; Tingy meant a string.

These phenomena of speech show a correspondence with certain nations and races which have given up the use of sounds common in languages of all other nations. The Chinese have no R in theirs; the Mexicans neither B, V nor F; the Iroquois and Mohawks are said to have no labials. A great deal of the inar iculate habit of imbeciles may be attributed to the laziness of imbecility.

This interesting boy, Johnnie McB., with the atrophied right arm and stammering, choreic speech, should demonstrate for us, some day, the localization of his brain lesion.

Mary P., interesting in the annals of surgery, for the successful ligation of the common carotid of the right side, to arrest a fatal hemorrhage, caused by a deep ulceration of the neck following scarlet fever. Her life was saved, but an extraordinarily bright intellect was sacrificed; left hemiplegia was complete, and the intellectuality of the child gradually failed after the operation. The atrophy and paralysis have not increased in the last seven years, owing, I think, to the

persistency with which the poor girl has taken her place in all the calisthenic and dancing exercises of our halls; re-education of the speech centre and a repossession of much of the former intelligence, is the satisfactory conclusion of seven years' residence in this Institution.

Of this class—imbeciles of the third grade—I present also Frank C., one of three brothers, illustrative of a somewhat rare affection—pseudo-muscular hypertrophy. The disease has not been traced back into the ancestry, as is usually the fact; the mother was not strong minded, and was afflicted with epilepsy. There are two daughters of marked physical beauty and of common intelligence.

Time will not permit more than the presentation of six very interesting children, whom I class with the juvenile insane. Two of them, Tom McK. and Annie W., are fully described in a paper on Juvenile Insanity, which was published with the Transactions of the State Medical Society, 1879.

AN EYE PROTECTOR FOR USE WITH THE MONOCULAR MICROSCOPE.

BY L. BREWER HALL, M.D.,

Of Philadelphia.

(Read before the Northern Medical Association, of Philadelphia).

So many physicians use the microscope, or are interested in the care of the eyes of those who do so, that I present this evening a little appliance, designed to be used with the monocular instrument, for the purpose of protecting the unemployed eye.

We are all of us more or less familiar with the loss of vision accompanying squint, and the prevention of it by the use of proper spectacles; but do we recognize the fact that the failure to use is the cause of the loss of sight; and do we appreciate that our employment of one and the same eye at the tube of an optical instrument is the same practice that cost the squinting eye of childhood its power of vision?

So many of us are contented when we have trained one eye so as to be able to do acceptable work, that we think we cannot spare the time to discipline the other. If this process ended upon the withdrawal of the head from the instrument, the practice would be less dangerous, but the trained eye finding an unequal companion, performs reading and all other near work with greater ease than its fellow; sees so much more distinctly that the other is left without exercise, except for large objects, and becomes of less and less value as the process goes on.

I could point to those who have practically lost one eye by this process, and I think I am much below the warrant of fact when I estimate that one-half of all those who have used the monocular microscope any considerable amount during five years are MONOCULAR MEN *for all fine work*. I mean by this that every such person who can "resolve" one of the more difficult "tests" with one eye will find himself unable to do so with the other.

How often have we heard persons exclaim, upon looking into a binocular microscope for the first time, "Oh, how much easier it is to see with this instrument, and how much plainer everything appears," this with one field quite dark (which provokes a smile from an amateur). I am now fully convinced that we cannot ascribe such expressions wholly to dissimulation or flattery, and for the following reasons, viz.:—

When both eyes are left open and one is applied to an instrument, the two images, being unlike, confuse each other in the natural endeavor to blend them. This requires a mental effort to exclude the impression upon the retina of one eye and regard that upon the other only.

Again, when we close one eye by contraction of the orbicular muscle, or by pressure, as by the hand, we cause contraction of the accommodating muscle also, and of the other eye as well.

I have proof of this many times each day, while measuring the eye for spectacles, by means of the ophthalmoscope, but we are all familiar with the spasm in *both* eyes when a particle of dust falls under the lids of *one* only, and we are conscious of the effort, amounting almost to an impossibility before training, of keeping one eye open and the other shut.

Both these are at least factors in the fatigue or irritation that accompanies the use of a monocular instrument, and are strong reasons for employing a binocular one.

There are reasons in favor of a monocular microscope, but we need not stop here to discuss the comparative value of the two forms. It is to overcome these two difficulties and to facilitate the training of both eyes that I propose the use of an eye protector.

A number of these have been devised, among which a plain card, perforated and slipped upon the tube, has, perhaps, been the best; this has to be low down, to be out of the way of the face, and then, to cover the field of vision, becomes so large as to hide the stage, if not interfere with the adjusting screws.

Another consists of a plate extending horizontally from the ocular. In this the edge has to be

cut away to admit the nose, and that necessitates the use of the same ocular and the same eye continuously, or else demands so much time to remove and replace it that most operators think it hardly worth the trouble.

The form that I now propose consists of a small, opaque disk near the eye, supported by a wire extending from its *outer* edge downward, to a point on the tube low enough to be out of the way of the nose, then bent upward, parallel to the tube, but not touching it, and attached to a ring near the top.

I made mine of a piece of brass wire, No. 18, about 45 centimeters long; a loop at one end, 4 centimeters in diameter, covered with a piece of black paper folded over and gummed down, forms the disk. At the other end, I made a ring to fit the draw tube, and then bent the intermediate wire. I attach mine below the flange, on the draw tube, where there is no lacquer to be scratched, but if it should be thought desirable to attach it above the flange, then the ring ought to be covered with chamois, so as not to wear the polish.

The advantages of this form are, the small size of the disk and its support, interfering with the working of the instrument and view of the stage as little as possible. The support is not in the way of the nose; the support is elastic, not uncomfortable when touched by the nose, and striking it does not displace the stand; it can be rotated about the tube and used with either eye alternately; it can be easily adjusted to the eye distance of any worker; and, lastly, it is of so simple a construction that any one can make it for himself, at a very small cost, two or three cents only, in addition to the time.

COLD TREATMENT OF SCARLET FEVER IN A PUERPERAL WOMAN.

BY HIRAM CORSON, M.D.,
Of Conshohocken, Pa.

Mrs. Bridgett Farrell, aged 30, mother of four children, was confined with the last one Monday, November 7th. The eruption appeared moderately on the 9th, and continued to increase until the 14th, when I was sent for to see her, because the physician who attended her in labor had not returned to see her after the first appearance of the eruption. I was confined to bed at the time, and as nothing was said by the messenger in relation to the character of the disease, the young physician who was attending to a few patients for me went to see her. He found her covered with bright eruptions of scarlet fever, with a temperature of 103°, pulse, 130. On inquiry he learned that the doctor who attended her on Monday, the 7th, saw her again on Tuesday, the 8th, and again on Thursday, the 10th, when he found her with an eruption and other symptoms of incipient scarlet fever. After that he came no more, and on the next Monday, the 14th, four days after his last visit, she was first seen by the young physician. He came back and reported the case to me. The child had been taken from the breast.

On hearing his statement, I directed him to return and ascertain whether the former attendant was not still expecting to take care of the case, and if not, to put her under the following treatment:—

But first let me restate her condition: She had been for four days with the eruption of scarlet fever; her head was aching violently; she was extremely restless; pulse 130; temperature 103°, as nearly as could be ascertained, her restlessness and tossing of her arms precluding accuracy in taking the temperature; her throat not very sore, nor much swollen; the muscles of the forearms twitching greatly.

It will be remembered by those who have read what I have written on scarlet fever during the last thirty years, that I have stated that in no case in which the head is much affected in the early stage, is there a very swollen or highly inflamed throat.

In this case I saw that condition was present; an affected brain dominating disease elsewhere. My directions to him, then, were, to go back, taking with him my nephew, from Norristown, who had seen much scarlet fever, and was conversant with my mode of applying cold to the head, and to use the cold in the following way: Never mind that this woman has just been confined; disregard her having scarlet fever; aim to relieve the head, by *pouring* cold water, ice water if need be, upon it; let one draw her head over the side of the bed, and the other *pour* half a gallon of cold water on the forehead, moving the stream from side to side, and on the top, till it is cooled off; even if it requires to be repeated several times; then return her to bed, with directions to have it repeated every fifteen minutes during the time till next morning; also, if the body be very hot, to occasionally sponge the whole body; to use some chloride of potassium for the mouth; give milk as food, and apply cold cloths, ice-water cloths, to the outside of the throat; but this last need not be considered very important; indeed, the one great object of treatment is the relief of the brain.

The next day, Tuesday, found her, early in the morning, worse. The women who were with her during the daytime had followed the direc tions for the pouring on of water and sponging, pretty faithfully, but when evening came, one of them had to go to her own family, and the old woman who was left with her was quite unable to do much in that way through the night, so that he found her on Tuesday morning entirely delirious; knew no one; talked wildly and was extremely restless, with increased twitching of the muscles. The doctors then took her fairly in hand, and the application of the cold was made in the most efficient manner all that day and the next night, and by Wednesday morning she had become quite rational. The treatment was continued, but more moderately, and a large bladder, partly filled with ice and with sufficient water to serve as a water cushion, kept constantly on the head; the body sponged frequently, from head to feet; milk given freely, etc.

It is useless to detail the particulars; suffice it to say, that on one occasion some quinine was used, and after the brain was relieved, the patient continued steadily to improve, until a copious desquamation took place—whole flakes of the surface coming off. I might say, too, that after the brain was relieved, the heat diminished and the pulse lessened in frequency. The young doctor thought it important to put two teaspoonfuls of whisky into every tumblerful of milk. It made me smile to hear him tell it, and I felt that it was to be expected that he would think it important, as it had been drummed into his ears day after day, during three winters, that whisky was the great medicine, without which no person could reach health; all other medicines might be left unused, but whisky never.

I have had a few scarlet fever cases since, but they were of a mild type, requiring only a moderate application of cold to the throat, cold drinks, some laxatives, etc.

But since my last writing to you on this disease and diphtheria, I have seen announcements in our newspapers of the deaths of five children in each of two families, in the upper part of Montgomery county and the town adjoining part of Berks; also deaths of three or four in a family in another county. I know that in these cases the cold treatment was not used, and I therefore feel that I ought to give a wide circulation to the facts, which testify to the value of ice as a remedy in these diseases, so fatal under the old, hot, stimulating, caustic-stuffing treatment. To this end, I intend, as soon as I can find leisure, to publish in pamphlet form various papers which I have written since the year 1840, and which are scattered about in your journal, and other medical journals, and in the State Transactions; to which I shall add my recent experience and the testimony, favorable and unfavorable, written by others, that I can extract from reports of societies, etc. I know, Mr. Editor, that you do not approve this plan. Now, while I respect your judgment, and believe with you, that it may not be the best in a financial view, still, I think it will best serve my purpose, namely, to impress readers with the conviction that it is, of all modes of treatment, the most successful. And as I do not care to make money by it, indeed, expect to lose some, I only ask of you now the privilege, just here, to ask the readers of your journal, who have at any time, during the last forty years, been induced to try it, to please send to me, by mail, at their earliest convenience, their experience with this means of cure, stating distinctly the kind of cases, their mode of application, how long persisted in, etc.

I shall add to my papers on ice treatment some experiences with ice as a remedy, in other affections.

Hospital Reports.

A CLINICAL CONFERENCE IN THE WARDS OF THE PHILADELPHIA HOSPITAL.

BY JOHN M. KEATING, M.D.

Reported by W. A. Edwards, M.D., Assistant Pathologist to the Hospital.

Croupous Pneumonia in Children.

Gentlemen:—It is my purpose to devote several hours each week to the practical portions of a course on children's diseases, in order that you may have the advantages of the treatment of this Hospital, to illustrate, and thereby bring more forcibly to your mind, what I endeavor to portray verbally at our meetings at the University. The first case of an acute character that we notice in this ward is this child, just admitted. I understand from Dr. Fairfield, Resident Physician, that the little patient has been in the house before; a few days ago the mother took it out. The child is two and a half years of age, has always been healthy, and has exhibited no evidence of any of the four diatheses.

Let me call your attention to its appearance as it lies in the mother's lap. You notice that it is restless and uneasy; its breathing is short, quick, and imperfect; expiration seems more pronounced than inspiration, and is not as noiseless; in fact, there seems to be forced expiration, with an expiratory groan, as if, in effect, the child endeavored to make its inspirations more easy by fully exhausting the volume of air contained in the lungs, thus avoiding unusual distention of the lungs by deep inspiration.

You will notice that it lies with its legs extended, hanging down over the mother's lap; the chest is thus made prominent. Such a position shows that the child is suffering from a disease supra-diaphragmatic. The child's intellect seems good, and it seeks, by its piteous glances towards the mother, relief from its suffering. I find there is a history of sudden onset, fever, and a short, dry, evidently painful cough. There has been no previous eruptive disease; no bronchitis attending the attack.

Let us listen to the chest. To do this thoroughly in a child of this age, it is well to have removed all superfluous clothing, poultices, cotton wadding, or the innumerable flannel bands that encircle the children of the poor, and to leave only one layer of material, either the flannel undershirt or its night-gown, between your stethoscope and the chest; be careful that the surface is smooth. Young infants are better placed upon the attendant's shoulder, which will give you the whole surface of their back to examine; a child of this age can lay across the mother's lap. You can thus be sure that the surface is even, and thereby make your comparisons of the sounds of both lungs more accurately. I would advise you, before auscultting the child, to examine the pulse beats and respirations, and I might also have added that it is advisable to take the temperature before the excitement of an examination; if the child is sleeping while you are getting from the attendant a short history of the case, you can readily introduce the bulb of a thermometer into the rectum; otherwise, if the child be awake, I would advise you to let the mother do this for you, and your note of temperature will then be accurate. I would always advise you to take the rectal temperature in an infant less than a year old; it is more accurate and easier obtained.

Let us return to the physical signs: you should accustom yourself to the use of the stethoscope in the examination of children; by it you will obtain more readily the sounds from limited areas, and you will be able to divide the sounds into their component parts, and distinguish the harsh, blowing respiration of consolidation from the breezy, exaggerated breathing of normal puerile respiration. Here you will encounter your first obstacle. The child will not obey you, and breathe at your call; it will not take a long inspiration, slow and deep, as would an adult, and thereby permit you to analyze the sounds, but its breathing will be shallow, rapid, irregular; there will be, as we notice in this case, a groaning, prolonged expiration, with feeble, quick inspiration, giving you scarcely time to catch the sounds before the act is over.

You place your stethoscope at the lower angle of the scapula, on the right side, and after a few respirations you note that occasionally you hear a fine, moist râle—you hear it both on inspiration and expiration; this fine subcrepitus is heard throughout the whole chest on the right side, and if you listen carefully, anticipating the respiratory effort, you can occasionally catch it at that time, and you will note that it possesses all the qualities descriptive of the crepitant râle. Place your stethoscope on its left back, and you will fail to hear such sounds; here you get a louder or more marked inspiratory whiff, and a softer, though equally distinct expiratory sound.

If you have ever listened to a child's chest while it is crying, and noted the exaggerated respiratory sounds that accompany the breathing intervals of its crying spells, you will understand the difference between exaggerated puerile respiration and that which is normal.

Bear in mind, also, that laryngeal obstruction may change the character of sounds of air entering the lung, also of the expiratory murmur; with this we have nothing to do at present.

In the case before us, you have carefully listened over the entire back, and noted the exaggerated respirations, rather harsh, and associated with subcrepitant and occasional crepitant râles on its right side, having as a focus of greatest intensity a spot about two inches square at the lower angle of the scapula.

Now you place your hand firmly upon its back, the fingers remaining at right angles to the child, and note any difference in the vibrations accompanying respiration; you can particularly distinguish a difference during the expiratory groan, and the occasional dry, hacking, suppressed cough. The vibrations are undoubtedly very much more marked on the right chest; this is another pathognomonic sign.

Gently percuss the back, beginning in the supra-spinous fossa of the scapula, first upon one side and then the other, using a firm but gentle tap with the finger accurately placed, alternating on the sides alike; note, as you descend, that the resonance becomes impaired upon the right side; at this point there is a decided higher pitch; note the resiliency is an elastic one, if I may use the term, not the flatness of fluid; still, there is no mistaking it.

You will also notice that the expansion of this lower lobe is not as quick as that of the opposite side, and if you listen once again you will find the voice of the child, during its cry, brought on by our examination, is never readily transmitted to the ear over this point.

We have, then, to sum up, viz. a child, previously healthy, not cachectic, a history of sudden onset, a temperature of 103°, a pulmonary lesion circumscribed, a bronchitis limited to one lung, or a portion of it, and the physical signs showing that the consolidation is compact, is capable of vibrations, and permits the introduction of air at least into the bronchioles, all of which, you know, is found in *croupous pneumonia*.

Your text-books, in order to illustrate the disease diagnostically, will place before you a distinct description of three stages, congestion, consolidation and resolution, but you will soon learn, at the bedside, that though these processes are distinct in themselves, they are associated in the case, they run one into another, by a line of demarcation so faint and illy defined as not to be distinguished except by their grosser signs, and that your stethoscope will soon make evident to you the subcrepitant and crepitant râle and the bronchial breathing, as you pass to its diseased lung. In this case, which is a type of its class in children, you have no *rusty sputa*, so important in the adult case, no well defined crepitant râle, to be brought out by your command, to deepen and show the respiratory act, and no

well defined exaggerated vocal resonance, unless your little patient should become irritable. How shall we distinguish this disease from *catarrhal* pneumonia?

The latter is lobular and scattered, not compact or lobar; it is rarely of sudden onset, following good health; it is accompanied by bronchitis, which is bilateral, and it is usually bilateral itself. It follows diseases which have catarrhal complications, in fact, is usually found in strumous and cachectic infants.

It is more frequent under 5 years of age, and is not so apt to cause the very high temperature of the other affection. But, as I have shown you lately, you may have sudden pulmonary congestion occurring during an attack of bronchitis of frightful intensity, intense bronchial and pulmonary engorgement, with rapid and profuse secretion or œdema into the bronchioles and air cells, in which death from suffocation or drowning can take place within a few hours. You have seen such a case, in which life was only saved by the most energetic treatment, the use of alum and brandy by the mouth, and the alternate immersion into hot and cold water, to stimulate the respiratory function. Such cases I cannot feel justified in attributing to cold alone, but I feel sure they are evidence of some central blood poisoning, either affecting the respiratory centre or causing vasomotor paralysis by its intensity or violence. But let me recall to you one other little patient in the Children's Asylum, whose case we studied together in clinic recently.

The child was four years of age, with no history beyond that of an acute attack of high temperature, with slight, dry, painful cough. A careful study of its chest gave us nothing but dry respiratory sounds, as would accompany the febrile state, and an occasional very fine subcrepitant râle over the left base. The temperature still remained about 102°, running up in the evening to 105°, with no further physical signs, but the cough was slight and painful, and the slightest movement of the body seemed to be productive of pain; upon the second day we noticed that the subcrepitant râle at the base was very fine and close to the ear, and was heard over the entire right base, and to some it became clear that it was a friction sound. Energetic treatment was instituted. Quinine by suppository, liq. ammon. acetatis, as a fever mixture, Dover's powder for the relief of pain, and poultices to the chest, with occasional warm baths and carefully regulated diet.

Gradually the morning temperature became reduced, but the evening exacerbations still remained. At the end of the third day we found the physical signs entirely changed. Now, instead of the pleural friction, we found the respiratory murmur more distinct, especially at the base of the lung; then the dullness on percussion became marked at this point, and gradually ascended; the difference on percussion and palpation became more distinct when the sides were compared, and soon its voice transmission was lost, or the sounds became far away. By comparison we found that the intercostal spaces on the right side were obliterated, and the effusion into the pleural cavity, for such there was, extended upward about three inches. I shall merely recall to your mind here, that we tested the value of non-interference in this case, when we said that the effusion had reached its limit without immediately endangering life, and that instead of using the aspirator to relieve the chest, as we had intended doing, and which should be done at once if you find the case suffering from the encroachment of the effusion, we placed the child upon potassii iodid. and syr. ferri iodid., by the mouth, and continued the quinia by suppository, and rubbed freely tr. iodine to the chest.

You saw the child gradually improve, the area of dullness diminish, and the child, when the parents rashly took it with them to another city, in a fair way toward complete recovery. It may often be of importance to you to remember the points of the differential diagnosis of that condition, and the one we are at present studying; especially should the question of aspiration come up before you as a remedy for immediate relief for impending fatal results.

To-day, we will place Baby A, in the first stage of croupous pneumonia, upon the following treatment. Large, thinly spread mush or flaxseed meal poultices, as hot as the child can bear them (to be tested by the hand), changed every three hours, and covered with oiled silk; as a rule, I prefer them to hot baths in this disease, though hot foot baths, with a tablespoonful of mustard, can be used twice to thrice daily. The bisulphate of quinia, gr. iij twice daily, by suppository to keep down high temperature, with instructions to use one of gr. v should the temperature register 105°.

We will also use whisky or brandy in ʒj doses, to aid the suppository in reducing temperature, if required; the understanding being to keep the temperature below 105°.

Do not forget the great importance of the frequent administration of nourishment, and I would advise you to make out for the mother or attendant, in all cases, a register of *diet* and medicine, to be strictly adhered to, for by it you can readily see what your patient is getting, and the quantity in the aggregate, of food especially, which you can increase or diminish as you see fit.

Should your little patients be fretful and sleepless, you can give two grains of Dover's powder, using the bromide instead of the sulphate of potassium, at night; we will use it in this case. Beware of draughts, especially when changing the poultices, but also see that the room is plentifully supplied with fresh air, well moistened.

Second Stage.—To-day, we again see our little patient. You will remember its condition three days ago. Place your hand upon the back, and you will notice, first, that the breathing is more regular; second, the temperature is reduced; it is now ranging from 100° in the morning to 101°, or slightly higher, in the evening.

The transmission of vocal fremitus is now clearly marked in favor of the right side, and percussion shows us illy defined and doubtful impairment; in fact, consolidation is complete. Your stethoscope gives you many more subcrepitant râles; those on the border of the solidified lung are of a coarser character; there is still harsh and prolonged expiration, and a blowing, roughened inspiratory sound, compared with the oppo-

site side. The mother tells us that the cough is looser, and upon questioning her I find that the stools, which are more frequent, are slimy. In fact, secretion is becoming established and resolution is setting in.

When shall we discontinue the poultices? When mucous râles are heard over the entire consolidated lung, and the temperature shows an abatement of the pulmonary inflammation, then you can replace the poultice by a thick layer of cotton wadding, changing it twice daily, and rubbing the surface of the chest with the following liniment:—

℞. Ol. succini, ℥ ij
Liniment. saponis, ℥ vj. M.

You may use cod-liver oil instead of ordering sweet oil in the liniment; in a few days I would advise the use of an external application of the following:—

℞. Tinct. iodini, ℥ j
Ol. myrrhæ; ol. olivæ, ℥ vj. M.
Sig.—Well rubbed in.

Let us modify somewhat the treatment of this case. You wish now to give tonic doses of quinia mixture in large amount, to reduce temperature, and you desire also to give *iron* in some form. For this purpose, a most valuable tonic is the elix. phos. quinia, ferri et strych., a well known preparation, containing in each ℥ j gr. j phos. quinia, gr. j phos. iron and $\frac{1}{60}$ gr. phos. strychnia; for a child of the age of two years you can give ♏ x three times daily; or you can order—

℞. Quiniæ et ferri citratis, gr. xij
Syr. limonis, f℥ ss
Aquæ, q. s. ad f℥ iij. M.
Sig.—Dessertspoonful three times daily.

Or,

℞. Ferri ammon. citrat.. gr. xij
Syr. amyg. amar., ℥ ss
Aquæ, q. s. ad f℥ iij.
Dose ℥ ij-iv.

and give the quinia still by suppository.

Quinia is a most desirable drug in this stage of the disease, the reason for which is that you should attempt to anticipate any attempt at suppuration or the breaking down of the consolidation and the involvement of the alveoli in the change; really the quinia is more valuable than the iron at this moment, and if one is to be sacrificed it should be the latter. Some children soon get accustomed to the bitter dose, when given with a little syrup and water, and then you will have no difficulty in administering a grain two or three times daily. Liquorice is the most useful excipient, and in a powder, as the following, is at times readily taken:—

℞. Ext. glycyrrhizæ ammonat., gr. j
Quiniæ bisulph., gr. j. M.
Ft. chart. No. j.

The French have used the tannate of quinia. Theoretically it would seem inert, on account of its insolubility; practically it seems to have been followed by sufficient success to have again established a position in children's practice.

The bromo-hydrate of quinia is a preparation I am very partial to, especially when quinia has to be used in large doses; it seems to be equally active, and devoid of the disagreeable head symptoms.

But let us return to the study of the treatment of the case before us.

The child's cough is loose, but still annoying, and a more stimulating expectorant will take the place of our first mixture. We will now give—

℞. Ammon. muriat., gr. viij
Syr. scillæ, ♏ clv
Tinct. opii. camph., ♏ xxiv
Syr. tolut., q. s. ad f℥ ij. M.
Teaspoonful three times a day;

and if the secretion is free, and you think it advisable to act gently on the intestine to carry off the accumulated mucus, you can use—

℞. Liq. pot. citratis, f℥ j
Syr. pruni. virg., f℥ ss
Glycerinæ, q. s. ad f℥ ij. M.
Dose ℥ ij-iv.

Some children seem utterly devoid of sufficient power to relieve themselves of the accumulation of the profuse secretion, the bronchial tubes become clogged with tenacious mucus, the stomach and intestines become coated with it, without power in themselves to cast it off.

Occasionally it will be well to administer a laxative, as a simple mixture of castor oil, aromatic rhubarb and glycerine; or if the secretions have failed to leave the trachea and large tubes, it is well to give an emetic, which you know acts so harmlessly in children.

By the latter means especially will this obstacle be most readily overcome. You know how frequently in this house, I advise the mother, in cases of bronchitis or whooping cough, to frequently change the position of the child for this purpose, placing it on its stomach and partially elevating the body, so that gravity will aid in expelling the collected mucus.

Third Stage.—To-day we again study our little patient: you will notice that we no longer use the poultices; they have been replaced by cotton wadding. You will also notice that the chest over the consolidated lung has been painted with tinct. iodine; in fact, the disease has passed to its third stage, that of resolution.

The râles are now no longer subcrepitant, but are large, mucous, heard everywhere; air is re-entering the portion of lung that was diseased. The percussion note is becoming lower pitched, and there is much less difference between the sides.

The cough is less frequent, is no longer painful, and the amount of secretion, known by inquiry as to the condition of the passages, is lessened.

The temperature is assuming a different phase; in the morning it is normal; toward afternoon, as you at present note, there is a slight rise, a hectic flush. The child is showing the effect of so exhausting a disease, and the slight suppuration, which in the adult would be noted by the yellow sputa, prove that the fibrinous plugs which lately filled the air cells are, in their turn, undergoing softening, and are partially expectorated and partially absorbed.

Now once more begins a critical period of your case. The child may succumb to the weakened condition; it needs supportive treatment—iron in particular, quinine, milk punch or wine whey, cod-liver oil, with the phosphates and the hypophosphites.

If the child had been previously exhausted, or cachectic, or if it should have been the subject of an inherited diathesis, now is the time when such inheritance would claim its mastery. You fear an extension of the suppurative processes a breaking down of the lung tissue, a phthisis, in other words, with the formation of cavities or caseous change.

The child before us was healthy at its birth; it exhibited no signs of inherited or acquired diathesis; it was strong and healthy when it left the house, and so far it has resisted the onset of a sthenic disease; but when it was re-admitted, the other day, the mother developed *delirium tremens*. The nourishment the little one received was such as to deprive it of any resistance to the slow, but equally sure, exhausting process which is now taking place.

We will now give it—

℞. Syr. ferri iodidi, ℥ j
Emul. ol morrhuæ, (fifty p. cent) ℥ iij. M.
Sig.—Dessertspoonful t. d.

Milk punch; half ounce of whisky or brandy in the 24 hours, increased if needed, every afternoon, just before the hectic flush appears; a suppository of 2 grains of quinine.

The tinct. iodine to be painted over the back daily, the child to be well wrapped and taken, during the middle of a clear day, into the open sunshine. It should also have a tepid bath (salt water) every morning, or if it be restless at night, the bath had better be given before bedtime

Varicella, Modified by Congenital Syphilis.

The next case that I have to show you, this woman and her baby, is of peculiar interest; the mother is suffering from syphilis and the child from varicella; the interest lies in the fact that the infant is also suffering from congenital syphilis, which causes an interesting modification of the eruption as we shall see later on.

The mother, Annie O., was admitted to the house on October the twenty-second, 1881; she presented a well marked syphilitic rupia, which had gone on to ulceration over the tibia and malleoli. The woman was at once placed on an anti-syphilitic treatment, to which she responded rapidly; on November the twenty-seventh, 1881, she was delivered of a female child, that presented no traces of syphilis on the cutaneous surface, but a short time after birth it suffered from *snuffles*, which is, as you know, such a common affection in these children.

The mother's anti-syphilitic treatment was continued, the child receiving its medicine through the medium of the mother's milk.

When the infant was three months old it was vaccinated with bovine virus; on the fourth or fifth day the arm became sore; but it was not a typical vaccination, or, in fact, was spurious, leaving no scar whatever. Synchronously with the development of the sore on the arm, a specific eruption appeared, confined to the buttocks, thighs and face. The eruption was of the papulo-squamous variety, with deep coppered-colored staining around the base of the papules; at this time the child also suffered from coryza, sore eyes, etc.

The mother was at once ordered increasing doses of the bichloride of mercury and the iodide of potassium; the child was simply allowed to nurse on the mother's milk, and thus absorb the anti-specifics; under this treatment the infant rapidly improved, and finally the eruption disappeared.

About a week ago a general epidemic of varicella broke out in the obstetrical wards, this child being affected with the rest; at first the eruption was simply the characteristic one of varicella, which, as you can see by these other children, is simply a vesicle, not surrounded by any inflammatory redness; these remain vesicles, and do not usually become pustules; occasionally the contents become tumid, owing to presence of pus; they attain their height on the third or fourth day of the eruption, then burst and shrivel, without presenting depressions at their apices; the crust, which will fall off in about five days subsequently, will be followed by a smooth, shining, round and irregular pit.

In this case, as you see, instead of a simple, isolated vesicle, appearing in crops, we notice that they are confluent, several having run together; they are also copper colored, the deepest staining being at their bases.

When the eruption has become confluent, it has an eczematous appearance; this is especially noticeable where we have heat and friction. In other portions of the body the eruption partakes more of the appearance of syphilitic psoriasis. *Microscopical examination* of the contents of these vesicles, made by the microscopist, Dr. H. F. Formad, and the assistant pathologist, show them to be crowded with micrococci zooglœa; none are seen within the white corpuscles. Examination of the blood, taken from the child's finger, shows the entire absence of micrococci in that fluid. The mother shall continue the same treatment, and the child will receive its mercury and iodine through the mother's milk.

Insurance by Medical Men.

We note from the Glasgow *Medical Journal*, that according to a scheme worked out by the Edinburgh Insurance Company, a medical man, by paying a fixed annual sum (say $150, if he be 30 years of age), will secure the payment of $5000 to himself at the age of 60, or to his heirs, should he die before that age. Then, if it be preferred, the $5000 may be converted into an annuity, payable during his own or his wife's, or their conjoint lives. If a member should at any time cease paying his premiums the company will pay, on his reaching 60, or at his death, a larger sum than he has paid in premiums. Thus, if a person during seven years has paid $1060, he will receive at 60, or his heirs will receive at his death, $1165. This is an example well worthy of imitation in our own country.

Editorial Department.

Periscope.

Pulmonary Abscess Opened Antiseptically.

In the *Lancet*, April 15th, 1882, Dr. Henry Payne records the following case: A young, healthy man, with no hereditary taint, was admitted into the hospital with well marked signs of pleuritic effusion on the left side. The trouble commenced six months before, with chills, pains in the left side, and feverishness, from which he was relieved by medicine and blistering the side, when he was able to continue his work for two months, at which time he commenced to experience difficulty in breathing and slight cough. He said he had spat blood once or twice. These symptoms becoming worse, and being unable to work, he was admitted into the hospital, June 22d, 1881. The side was painted with tincture of iodine, and iodide of potassium with cod-liver oil administered internally. This treatment was continued until August 20th, without any improvement, when the following signs were noticed. The patient has lost flesh since his admission; the left side of the chest bulges more than the right, and measures an inch more around; movements on this side are deficient; there is absolute dullness on percussion, both back and front; no breath sounds are heard, and the vocal fremitus and resonance are absent. The breathing on the right side is exaggerated. The cardiac dullness is continuous with that of the rest of the side; no apex beat can be seen or felt, and there is no displacement. Upon auscultation, aortic murmurs are heard, and the pulse is of the "water hammer" character. He has night sweats; temperature every evening is above 100°, and the pulse invariably above 100. Empyema was suspected, and an exploratory puncture made in the sixth intercostal space, in the axillary region, discovered pus. Accordingly, on August 23d, an incision, about two inches long, was made, just above and parallel to the seventh rib in the anterior axillary line, antiseptically and under chloroform. Upon opening the pleura, there was very profuse hemorrhage, of dark venous blood, which could only be arrested by the injection of a solution of the perchloride of iron. About fifteen ounces of pus escaped. Passing the finger through the wound into the cavity, there appeared to be a number of adhesions, some of which were broken down by the finger. A drainage tube was inserted. The dullness disappeared after the operation; the same side became hyper-resonant. Patient felt much easier, and could now lie on the right side for the first time since the illness. There was a very profuse discharge, which in a few days became fetid. He had now a very troublesome, irritable cough, with much frothy, muco-purulent, bloody expectoration. He continued fairly well until the 29th, when the temperature suddenly rose to 103.4°; he had great pain in chest, voice became very weak; perspired freely, lost his appetite, and gradually sank, dying on the morning of the 30th.

The necropsy showed the whole of both surfaces of the left pleura adherent, without a drop of fluid in the sac. The external opening made in the chest wall led into a large, irregular cavity, situated in the centre of the lung, which was in a state of grey hepatization. The opposite lung was healthy, but congested. The heart was small and flabby, and the valves healthy. Other organs normal. This was evidently a case of chronic pneumonia, ending in the formation of an abscess. It is interesting on account of its rarity and the difficulty of diagnosis. Trousseau failed to meet with a case during his first twenty-five years as a hospital surgeon. The difficulty in diagnosis has been made apparent, by the symptoms already described, which pointed so strongly to empyema. The question might be asked, whether, if the case had been left to itself, would the abscess have ever opened and discharged itself into the bronchus, and so the pus be expectorated, or would it ever have burst externally? It could not have opened into the pleural sac, because that was closed by previous inflammation. The symptoms that were present after the operation were explained; the irritable cough and profuse purulent expectoration mixed with blood were due to the finger breaking down lung tissue, which was at the time supposed to be adhesions. The hyper-resonance was due to the cavity being filled with air. But one thing remains unexplained, the aortic murmurs when the valves were healthy. The only assignable cause is pressure

Fungosities of the Bladder Cured by Scraping With the Finger.

In the Boston *Medical and Surgical Journal*, Dr. Walter F. Atlee reports a very rare and interesting case.

Miss S. B. consulted me in the summer of 1880, on account of painful and frequent micturition, with hæmaturia. She was born in April, 1861: her father is a large, strong, and healthy man; her mother died when she was a child, after having suffered from many manifestations of scrofula.

She said she remembered to have felt, occasionally, a slight pain in passing urine, from her earliest recollection. When seventeen years of age she first suffered severely; her urine was then very light in color, with no sediment, but with a strong odor. The pain was while passing the urine and after it had passed; after the emptying of the bladder there was a constant desire to pass something more. She became thin, pale, and haggard. When eighteen years of age some pus appeared in the urine, and occasionally a little blood. These symptoms increased to such an extent that she was obliged to keep her bed for several months. This rest, aided, perhaps, by medical treatment, for she had always enjoyed the care and attention of our most experienced physicians and nurses, made some improvement in her condition, so that she was able again to go out. All the worst symptoms, however, soon returned, and when I saw her, in

September, 1880, her state was a very serious one; there was constant inclination to empty the bladder, which could not be resisted oftentimes for more than a half hour, and the loss of blood was considerable.

The urine, when examined at this time, showed pyoid bodies, epithelium from the bladder, and crystals of triple phosphate, together with blood corpuscles in abundance. The blood was of a bright-red color, showing that the urine had not time to produce those changes in color always produced by long contact with the hæmoglobin of the corpuscles.

With such symptoms, this case seemed clearly to be one of foreign body in the bladder, and the advice given was to attempt its removal without delay. For this purpose the patient was put under anæsthetics, and the urethra was dilated by means of a pair of ordinary dressing forceps, introduced opened, and withdrawn as often as necessary—this being, in my experience, the best way of effecting this dilatation.

When the finger was then passed into the bladder nothing abnormal was felt, no calculus, nor distinct tumors, except that about the fundus were a number of fungosities or soft growths, some of them more than half an inch in length, and about one line in thickness. These were carefully scraped off by the end of the finger and by the finger-nail. This simple operation resulted in the perfect cure of my patient, and until the present time there has been no symptom of a return of her disease.

I call the growths thus removed fungosities, and not villous growths, inasmuch as they were not like tufts of fine hair (*villi*), but resembled rather *fungi*, or certain mosses. I have several times seen similar growths removed from the cavity of the uterus, in cases where for years they had been the cause of alarming hemorrhage. They have, anatomically, the same fundamental structure as the mucous membrane whence they spring; they are simple excrescences of this membrane: they are formed of granular, amorphous matter, of cellular tissue in small quantity, and of fibro-plastic elements; almost all have a large number of capillary vessels ramifying through them, and some are covered by epithelium. This epithelium is *on* the surface, *homologous*, and not *within* the subjacent connective tissue, *heterologous*, which is characteristic of epitheliomatous growths.

Acute Traumatic Malignancy.

Dr. Henry B. Walker reports the following interesting cases in the *British Medical Journal:*

Case 1.—A master mariner, aged 53, was always healthy until fourteen weeks before death, when he was struck violently in the right hypochondrium by the shaft of a cart. The blow rendered him unconscious. He was laid up for two days, when, although feeling "very sore and ill," he started on a voyage. During the trip he was in much pain, and on his return was laid up again. Feeling better, after some rest, he took another voyage, but was so ill that he had to give up command. His symptoms were frequent vomiting, complete loss of appetite, intense pain in the region of the liver, shooting across the epigastrium. He was much bruised and very tender. On examining the abdomen, he was extremely tender all over the region of the liver in front, the tenderness extending to the left hypochondrium and down nearly to the navel. There were no signs of enlarged liver, but some jaundice, with pale stools and constipation. A fortnight later his condition became gradually worse, a well defined and tender bossy mass, with rounded edges, under which the fingers could be passed, was found projecting below the ribs (at a point which would be intersected by a line drawn perpendicularly from the anterior superior spinous process of the ilium), and extending well into the left hypochondrium. This mass, which was taken to be liver, extended downward and to the left side till it filled the abdomen in front to a level with the umbilicus. Its extreme hardness and the constant presence of sharp, lancinating pain, together with the cachexia accompanying it, led to a diagnosis of malignancy, which was confirmed by an eminent consultant. Toward the last week of his life the patient vomited a quantity of blood containing pyriform and oval multi-nucleated cells. After the last hemorrhage the patient died exhausted. A post-mortem was denied, but there was no doubt in the minds of three medical men as to the nature of the disease, and it was believed to be carcinoma of the liver, invading the stomach secondarily. There was no history of malignancy in the family. No history of dysentery or syphilis was attainable.

Case 2.—Mr. F., a farmer, was out shooting; and while he was trying to force his way through a hedge a thorn penetrated his trousers and wounded his prepuce, causing blood to flow. He took little heed of it at the time; but a few days later, feeling some heat and uneasiness, he found swelling and irritation about the wound. This rapidly increased, and he then consulted his medical man, who advised certain remedies. The penis grew worse, and the whole glans presented a mass of carbuncular hardness in a short time, and was very painful. An incision into it giving no relief, and suspicion being confirmed on consultation, the penis was amputated, and the growth proved to be epithelioma. This was only a few weeks from the date of injury.

Case 3.—A gentleman rode to hounds mounted on a very broad backed horse, and in the evening felt the inner side of his left thigh stiff and sore. The stiffness persisted, and was followed by a slight fullness, and finally, by a well defined tumor about the size of an orange, nestling among the deep muscles of the thigh. This was removed by operation, and proved to be a small, spindle celled sarcoma.

Case 4 was related to me by a lady whom I was attending in labor. Her brother was playing football, when he received a kick on the shin. This led to severe inflammation, which laid him up for some time. On apparent recovery, a hard swelling remained on the tibia, which soon began to cause pain and enlarge. As it increased and bore suspicious characters, the limb was amputated at the knee joint, but the growth recurred, and the patient lost his life. I asked the lady what the growth was, and she said, "The

doctors did not call it a cancer, but by a queer name—'sarcoma.'"

In all the foregoing cases, the patients confidently referred to their injury as the cause of the trouble; and in all except the last, I can state that minute inquiry failed to trace a family history of malignancy. In the last case, I have no note on this subject, and therefore cannot speak with certainty, but I believe I was assured that such was the case in this one also.

Extirpation of the Ovaries for Insanity.

In the *American Journal of Insanity*, January–April, 1882, Dr. Wm. Goodell contributes an article from which we extract the following:—

By the aid of Listerism, abdominal surgery has reached such a pass that many formidable operations involving the hitherto sacred peritoneal cavity are daily undertaken, with a success and a degree of safety as much assured as in surface surgery. Even exploratory incisions are boldly made, merely for diagnostic purposes. Hence it is that ovariotomy is now one of the most successful of the major operations. Hence it is that oöphorectomy, or the extirpation of the ovaries—not for any intrinsic disease, but merely to bring on the climacteric—has been placed on a firm basis.

The disorders of menstrual life for which the ovaries have been successfully removed are fibroid tumors of the womb, chronic pelvic peritonitis, persistent ovaritis and ovaralgia, ovarian epilepsy, dysmenorrhœa, menorrhagia, and, in short, for all those lesions which are brought about or which are intensified by the periodic congestions of menstruation.

To this list there can be no doubt that some forms of insanity ought to be added. The relation which they bear to menstruation is often a very close one—so close, indeed, that the term ovarian insanity would best define it. Thus all alienists have observed cases of mental disorders in which the periods of exacerbation correspond to those of menstruation. In the interval between the monthly fluxes the patient may be either wholly sane or at least quite controllable. Esquirol and Morel have gone so far as to assert that derangements of menstruation form the source of origin of one sixth of the cases of insanity due to physical causes.

Now it seems to me that, since the verdict of the profession is largely in favor of the removal of the ovaries for many physical derangements dependent upon menstruation, the same remedy should, *à fortiori*, be tried for those mental derangements which plainly arise, or seem to arise, from the same source. The objections to such remedy when applied for mental diseases, are, in fact, less valid than when it is resorted to for physical lesions. For, in the first place, an insane woman is no more a member of the body politic than a criminal; secondly, her death is always a relief to her dearest friends; thirdly, even in case of her recovery from her mental disease, she is liable to transmit the taint of insanity to her children, and to her children's children, for many generations. The removal, therefore, of the ovaries in such a case would then tend to restore a woman to home and to society, and it would at the same time effectually bar her from having an insane offspring. I am, indeed, not sure that in the progressive future it will not be deemed a measure of sound policy and of commendable statesmanship to stamp out insanity by castrating all the insane men and spaying all the insane women. But laying all speculation to one side, I wish now to give my own limited experience in the matter, and to put it on record, so that others may profit by it.

He then records the histories of four cases, in which the operation afforded relief. The relief is not immediate, but requires time, and for a cure it is necessary that the patient should be afforded change of scene and occupation in connection with the operation.

In conclusion, he says: "Let me make a few remarks about the mode of performing oöphorectomy. Until very recently, I have warmly advocated the removal of the ovaries by the vaginal incision, and, indeed, I would now perform the operation in that way were the ovaries so low down in Douglass' pouch as to be readily felt through the walls of the vagina. But the dangers and difficulties of such an operation, when the ovaries are high up, more than counterbalance its advantages. Twice have I failed to remove them per vaginam, and had to resort to the abdominal incision; and once, from the return of menstruation, I think that some ovarian tissue was left behind. For these reasons, and also because I have found so little inflammatory reaction following the larger operation of ovariotomy, I shall in future perform oöphorectomy by the supra-pubic incision, unless the ovaries are low down.

Infectivity of Scarlet Fever.

At a meeting of the "Society of Medical Officers of Health" (*British Medical Journal*) Dr. Alfred Carpenter read a paper on some of the causes which increased or modified the infectivity of scarlatina. He considered that a long period of quarantine—such as eight or ten weeks, and sometimes four months—was to be deprecated in the case of children recovering from scarlatina; he himself, for many years, had isolated cases for a fortnight, and in some instances for a week only, after the departure of the fever and he had never heard of any evil results accruing from such a course. He next mentioned various cases in large schools, which served to explain his views as to the causes of scarlatina. The first outbreak of which Dr. Carpenter made mention was, in his opinion, entirely caused by a cesspool situated in the school yard, which was the recipient of washings from a slaughter-house; and, once a week at least, the aerial contents of this cesspool were displaced into the closets of the boys, situated in close proximity to it. As soon as this cesspool was emptied, and the drains properly directed into the sewer, scarlatina ceased to appear in the school. Want of proper ventilation in the soil pipe and drains belonging to the building caused an outbreak of scarlatina in another school—the drains being in direct communication with the main sewer of the district, and scarlatina being also at that time very prevalent in the neighborhood. Dr. Carpenter be-

lieved that the nature of the blood into which the poison was received aided more materially in increasing the mortality from scarlatina than the character of the poison itself; and in support of this theory, he instanced two outbreaks of this disease, in one of which the mortality had been excessive, fourteen persons having died out of seventy-five who were attacked; and in the other outbreak only three deaths occurred, though the total number of cases was one hundred and eight. Dr. Carpenter attributed this difference in the mortality to the surroundings of the children; in the one instance, the conditions were, on the whole, healthy; while, in the other, the children were exposed for a much longer period to an impure atmosphere, and were badly cared for at home. The cause of the two outbreaks was similar in character: the excreta of the first case of scarlatina, in each school, passed down unventilated drains, which communicated directly either with class-rooms inhabited by the children, or with closets used by them. In conclusion, Dr. Carpenter said that he believed scarlatina more often arose from sewage emanations, or from sewage contaminated with scarlatinal germs, than from personal contact. He considered that, in many cases where the cause of the disease had not been discovered, it might have been found, on careful investigation, to proceed from some accidental inhalation of sewer-air; and that persons who were constantly exposed to such an atmosphere were liable to more severe attacks of scarlatina and diphtheria than those who inhaled the poison for a short period only. Dr. Carpenter also suggested that the discharge of hot water and waste from steam engines into the sewers was a source of danger, in producing scarlatina and diphtheria.

Action of Chloroform.

In the discussion which has for several weeks occupied the attention of the Academie de Medécine, regarding the symptoms observed during chloroformization, M. Vulpian, at a recent séance (March 28th), expressed the following opinions concerning the practical and experimental questions brought forward by the different speakers:—

The symptoms induced by chloroform are observed generally at three principal periods—either after the first few inspirations, or while the patient is gradually coming under the influence of the drug, or, again, within a few hours or even a few days after chloroform has been administered.

Excitation of the superior ends of the upper laryngeal nerves induces arrest of perspiration, and the same effect is obtained when one of the nerves controlling the upper segments of the respiratory organs is touched with a camel's hair pencil wet with chloroform. During his experiments M. Vulpian remarked that animals, dogs especially, do not support as well as man the action of chloroform. The symptoms observed are due to arrest of the heart (cardiac syncope) or to that of the respiration (respiratory syncope). Chloroform does not invade successively the different organs; it acts immediately and at once on all the tissues. The respiratory centre seems to offer a notable resistance to its action, but is not entirely spared.

If the pneumogastric nerve be divided in an animal under the influence of chloral or chloroform, the animal continues to breathe, notwithstanding the section of the nerve. Excitation of the central end determines sudden and immediate arrest of the respiration, lasting from one-half to one minute. Excitation of the peripheric end in a chloralized animal produces complete and definite arrest of respiration, and while in the non-chloralized animal there is but a momentary arrest of the heart, in the other the heart beat ceases and the animal succumbs. Anæsthesia acts, then, on the cells of the respiratory centres, also on those of the sympathetic ganglia, which control the action of the heart, and these ganglia are no longer capable of resuming their functions when these have been once abolished by any excitation, electric or otherwise.

In unfortunate cases, when all the organs are under the influence of chloroform, the animal continues to breathe and the heart does not cease beating; but if too large a dose be administered, or any excitation of the pneumogastric take place, then respiratory or cardiac dyspnœa supervenes and the animal succumbs. Symptoms may supervene while operations are being performed, when anæsthesia is complete, demonstrating that the cord conserves its powers of conduction, even when under the influence of chloroform; and that peripheric excitations are transmitted without cessation to the bulb. Under such conditions syncope, of bulbar origin frequently supervenes.

On animals cardiac syncope is of greater gravity than that induced by arrest of respiration, for in the latter case artificial respiration may and should be resorted to. M. Vulpian concluded by saying that chloroformization is never exempt from danger, as syncope is always imminent.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"The Mental Status of Guiteau," by Walter Channing, M.D., comes as a reprint from the Boston *Medical and Surgical Journal*, March 20th, 1882. The author maintains in this paper the insanity of the criminal, and concludes by saying: "It would have been much more to our credit as a country, much more in the interests of humanity and progress toward better things, and what is still more to the point, much more in accordance with a correct interpretation of the evidence in the case, as presented to my mind, if the wretched Guiteau had been consigned, as a lunatic, to a criminal insane asylum for life, rather than sentenced to the gallows as a sane criminal."

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

VENESECTION.

Since the venerable Prof. Samuel D. Gross took such a decided stand in favor of venesection —now several years ago—the subject has been more or less fiercely debated in all the more prominent medical journals of our country. The readers of the MEDICAL AND SURGICAL REPORTER will have frequently read articles *pro et contra* on blood letting, and of late the dispute seems to have gained new impetus, if we can judge from the correspondence we received, and some of which we recently published. While many writers recommend bleeding from a vein in all acute inflammatory diseases, the greatest difference of opinion seems to prevail in regard to blood letting in acute, lobar or croupous pneumonia. To us it seems as if the extremists of both views go a little too far, that they are committing the same mistakes which our forefathers made about half a century ago; they consider too much the name of the disease, and not sufficiently the constitution of the individual. It would lead us too far, were we to mention all maladies in which, of late, blood letting has again been recommended, but we may be permitted to illustrate our views, or rather, what we believe to be the teaching of modern science in reference to this question, on two diseases, in which venesection has been especially recommended, pneumonia and remittent fever.

What is acute, lobar or croupous pneumonia? Is it simply a croupous inflammation of mostly the lower lobe of the right or left lung, due to an exposure to cold? Decidedly not. The modern view, that it is an infectious disease, with a special tendency to the lungs, like diphtheria, with its formation of false membranes, mostly in the throat, or like typhoid fever, with its ulceration of Peyer's patches and solitary glands, or like any other zymotic disease, gains daily more adherents. The truth of this assertion is proven by the following facts. It is a disease of a certain definite duration, mostly ending by a crisis on the fifth, seventh, or ninth day, a thorough sweat being followed by a refreshing sleep and resolution. That cases occasionally linger a longer time is no proof to the contrary, as we see the same happening in other infectious diseases. Further, the lesion, which often, in fatal cases, does not extend further than to the stage of red hepatization, and is frequently confined to only the lower lobe of one lung, is not alone sufficient to account for death. We have in tubercular phthisis far more destruction of lung tissue, and the individual lives sometimes for years. Other important points in favor of the view expressed are, the abrupt beginning with a chill, or with flushes of heat, the high temperature, and the frequent early complication of the same œdema of the brain as we find in cases of typhoid fever, when the pia mater is filled with bacilli typhosi. Lastly, death sets in—not in consequence of the local lesion—but by failure of the heart's action. If we have an anæmic individual with a weak heart, or an old person, not plethoric, would we strengthen the main organ of circulation by venesection? Is a tonic treatment with digitalis, quinine, stimulants, and later carbonate of ammonia, not a far safer plan? But if we find a young, strong, and plethoric individual, with intense engorgement of the lung,

there the first indication is the relief of the blood pressure, and we bleed such a person from the arm, not on account of the pneumonia, but notwithstanding the pneumonia, on account of his general condition. It is not the name of the disease which induces us to open the vein. If a similar individual would be attacked by a severe congestion of any organ, and due to some other cause, the same practice would hold good.

How should we proceed in remittent fever? At a time when venesection was fully in vogue, 75 per cent. and more died of remittent fever. James I, Cromwell, Charles the Great, and many other eminent persons, who could and did command the services of the most prominent physicians of their time, had to die of this disease. But what is the reason that, since the general adoption of the American practice, of giving quinine in daily doses of from twelve to sixteen grains, from the very beginning and all through the disease, the mortality is only 2 per cent.? Remittent fever is due to malaria; quinine is a specific against this poison; is it not more than logical to make use of this remedy as early as possible, and as long as necessary? No bleeding will here do any good; a venesection may cut short the cold stage of an intermittent fever paroxysm, but it will not prevent the recurrence of other febrile seizures nor ever cure remittent fever. We are aware, however, that the latter malady is often complicated by subacute meningitis. If this is severe and accompanied by a hard, tense pulse, then, if the patient is seen early, we would recommend blood letting from a vein, as in certain cases of acute meningitis, but not neglect the specific treatment. Notwithstanding a practicing physician of ripe experience is mentioned as authority, we will never believe in the cure of a genuine case of remittent fever by one or two venesections alone, and without the employment of quinine, or some other preparation of the Peruvian bark. To teach such a practice is exceedingly dangerous. We have in this malady, again, an illustration not to bleed on account of the disease, but because a certain condition of the patient indicates this therapeutic measure. If the hard, tense pulse and the subacute meningitis are not present, there is no need of bleeding, be the individual plethoric or not, as we have convinced ourselves frequently in private and hospital practice.

In conclusion, we will mention only one disease more, to prove conclusively how dangerous it would be to practice venesection in general without paying the utmost attention to the patient's exact condition. This malady is apoplexy. Formerly it was the practice to bleed in this disease. What does modern science teach? There are four main forms of apoplexy. In one the attack is due to active congestion (sudden but only temporary unconsciousness and transient paresis, with congested face, injected eyes, throbbing carotid, full, slow pulse); in the others to bursting of a blood vessel in the brain (long continued unconsciousness, followed by more or less lasting hemiplegia, face congested, pulse slow and full); in the third to embolism (presence of valvular disease of the heart, none or only momentary unconsciousness, mostly a sudden stroke of paralysis, face pale, pulse small and rapid); and in the fourth to serous effusion (mostly in Bright's disease, very pale face, dilated pupils, total unconsciousness and utter insensibility, often convulsions, pulse small, frequent and irregular, always rapidly fatal). The rule as regards venesection in apoplexy is, at present, bleed in the congestive form always, if the patient has not regained consciousness before we arrive; and in the hemorrhagic variety, if the pulse is very slow and full, and improves under blood-letting; but never bleed in cases of embolism or in the serous variety. We have, therefore, here once more the same rule: if you want to practice bleeding at the arm, be guided, not by the name of the disease, but by the condition of the patient. Apoplexy from active congestion is met with only in plethoric persons; if there are minute aneurisms and the bursting of one or more of them has caused the hemorrhagic variety, you will do good with venesection to relieve the blood pressure, but the pulse must be slow and full; if the latter is rapid and irregular there is no use in venesection; the effusion is too large, and death will take place under all circum-

stances. That blood-letting will be of no benefi' in the other two varieties is too apparent to need further comment.

The modern practice regarding venesection, as well as all treatment, is undoubtedly the correct one: whenever attending a patient, base your therapeutic measures upon the general condition of the patient, but at the same time do not ne glect the special indications the underlying dis ease offers; or, in other words, study thoroughly the *pathology of the case*, before you begin any active interference.

Notes and Comments.

Foreign Body in Œsophagus followed by Emphysema.

In the *Lancet*, W. Lewis Morgan reports the following case: A woman, aged 54, had just put a piece of pork in her mouth, and turning to say something to her child, the piece of pork "slipped back into her throat." This was followed by severe paroxysms of coughing and great difficulty in breathing. In a few hours her face began to swell. The face, neck and upper part of the thorax became much swollen and emphysematous. The loose cellular tissue beneath the lower eyelids was greatly puffed out. An attempt was made to pass an œsophageal bougie, but it was stopped at six inches by some obstacle. Ether was then administered and two more attempts were made to pass a bougie; the second was successful, the instrument passing into the stomach. It could be felt to push something before it. When the patient recovered from the effects of the anæsthetic she could swallow much better, but still the attempt caused great pain and spasmodic cough. She was discharged after ten days, well, the emphysema entirely gone. The piece of pork which caused the mischief was only just taken into the mouth, and consequently had not been at all chewed; it was all meat, without any bone. It seems difficult to account for the supervention of surgical emphysema; one would be inclined at first to ascribe it to some injury the result of an attempt to pass an instrument, but there can be no doubt, from the patient's account, that the swelling was previous to all surgical interference, and, in fact, was the cause of the patient's friends seeking medical advice. It has seemed to me that the phenomena may be explained by supposing that the meat, when first suddenly bolted, lodged in the back of the pharynx, over the entrance to the air passages; that this caused sudden and severe fits of coughing and spasm of the glottis; during these great expiratory efforts the trachea may have been slightly lacerated, or rather torn, and thus air would have been forced into the surrounding cellular tissue at each succeeding paroxysm of coughing; but I must confess that the explanation is not quite satisfactory, for one often sees patients afflicted with severe paroxysms of coughing and yet no rupture of the trachea takes place. The piece of meat could not have lacerated the œsophagus or trachea, for the patient is quite positive it was only lean, without bone. The subsequent history of the case would be against the food having passed directly into the air passages, although it might at first have lodged in the pharynx, and compressed the upper part of the larynx for a little time, then passed just down to the junction of the pharynx and œsophagus, whence it was pushed by the bougie into the stomach.

Hydrocele of the Neck.

At a recent meeting of the Glasgow Medico-Chirurgical Society (Glasgow *Medical Journal*), Dr. James Whitson reported a case of hydrocele of the neck. He first spoke of their extreme variety. The patient was a girl, 7 years of age, and the hydrocele was situated on the right side of the neck. It had first appeared when she was 5 months old, since which it had gone on increasing in size, but had never caused any inconvenience. The head was carried slightly to the left side. There was an oblique depression in the tumor corresponding to the sterno-mastoid. On August 14th, 1881, it was evacuated by the aspirator and continuous pressure afterwards applied. By the middle of November the cyst was as large as ever, and on the 18th, with antiseptic precautions, an incision was made into it. When it was thoroughly evacuated, tincture of iodine was applied to its interior by means of a brush. Decalcified drains were then introduced, and the wound dressed. Five weeks after operation the wound was healed, and the hydrocele has been completely cured. In discussion, it was considered that this mode of treatment was an improvement on the old method. Stuffing the sac with lint had been tried, but it set up a great deal of inflammation and caused puckering of the skin. Setons had also been used. One case was mentioned where the cyst had been washed out with chloride of zinc, and the result was good.

Hysterical Retention of Urine in a Man.

Dr. James Russell reports the following case in the *Medical Times and Gazette:* A man aged forty-one was admitted into the hospital complaining of complete inability to pass his urine and of defect in the free use of his legs. He brought with him a flexible catheter, which he kept by his side, by means of which he emptied his bladder three times in the day. His statement was that during the preceding fortnight he had experienced difficulty in walking, and that a week before entering the hospital he had suddenly lost the power of expelling his urine. He endured the retention of urine until the following day, when medical help was summoned and a catheter was passed without difficulty. He was at first supposed to be suffering from a paralytic affection, but further investigation threw doubt on the accuracy of this opinion, and confirmed a suspicion suggested by the very sudden manner in which such complete paralysis of the bladder appeared to have been effected. The man was very nervous, and eighteen months previously had experienced severe protracted mental strain. This was followed by a nervous tremor, especially when he was worried, which prevented him from sleeping. The urethra freely allowed the passage of a large sound and the prostate was healthy. There was a scanty deposit of leucocytes, but in other respects the urine was healthy. The catheter was permanently withdrawn, and the patient was told that he must send for one of the resident officers if he wanted his bladder emptied. The effect was almost immediate; on the following day or day after he passed his urine spontaneously, and from that time had no further trouble in this respect. The power of walking was recovered gradually.

In this case the sequence of events was very plain, and shed an interesting light on what probably occurs in many cases of hysteria. We have, in the first place, a morbid condition of the nervous system, consisting in a highly sensitive state of the recipient centres, engendered by much anxiety, acting on nerve-tissue already by predisposition intolerant of any unhealthy influence, as indicated by the nervousness, the tremors, and the sleeplessness. The effect of the limb-pains, in themselves by no means severe, in restricting the free use of muscles and joints to such an extent as to interfere with locomotion, pointed to morbid sensibility to pain. Under these circumstances urethral irritation of a very mild character (for it was never spoken of afterwards) was set up—possibly rheumatic, or connected with the previous gonorrhœa, indicated by the leucocytes in the urine—and pain was produced in the urethra by the presence of urine. As a result, the pain in the urethra, just as the urine had entered the neck of the bladder, consumed the whole attention of the patient, and he forgot to exert the normal cerebral influence which is requisite in order to control the inhibitory centre of the vesico anal apparatus; the reflex activity of the sphincter vesicæ thus remained in full activity, and the passage of urine was effectually barred.

It is hardly necessary to recall the generally received opinion that a controlling centre probably exists in some part of the cord at a higher level than the genito-anal centre, which governs the action of the sphincter vesicæ; and further, that every one's experience supports the result of observation, to the effect that the controlling centre in the cord, or (if that do not exist) the entire urinary muscular apparatus, is subject to the influence of the cerebrum.

The case has much analogy with hysteria, both in its substratum of an abnormal condition of the nervous centres, and in the presence of some local defect as the immediate cause of the morbid development; as, *e. g.*, witness how many cases of hysterical aphonia start from an ordinary catarrhal sore-throat.

The African Treatment of Insanity.

The *American Journal of Insanity* contains the following from the *Asylum Journal*, British Guiana, October, 1881, which, from its originality and the hints it contains, may prove of interest and service.

The following letter received from the wife of an aboriginal African now a patient in the Asylum tends to controvert the opinion held by some that insanity is unknown on the dark continent. It shows that it is sufficiently common for its hereditary character to be acknowledged, and for a recognized method of treatment to be formulated. Many alienist physicians in more enlightened countries may well envy the certainty with which a cure is effected in three months, and if the same result could be promised to them they might be inclined to try the plan. Although non-restraint and soothing principles of treatment are adopted it will be seen that prolonged seclusion is enjoined. Like the gods of old, the patient must have a special food and drink: unfortunately what these are is not specified. Does this not resemble the colored light treatment so lately in vogue in Europe, and is it much more irrational than it? "I came to the Doctor to let him understand about my husband's

sickness. So Master he is not a native for this country, the sickness he is troubled with is not a sickness for him to be here, some of his countrymen from Georgetown made me to understand so. They did went up the river to see him, so I tell them he is in the charge of the Doctor, they say that this sickness is from their country, it is the gift of God from their country from generation to generation as far as they know. If they were he wouldn't have been here to-day, because we would have know what to do to keep down the sickness from him. Sir the sickness don't require no noise at all, he must be in a house him alone and those who attended to him and they does not use him every kind of food, purpose food must be for him, and he must close him in a house for nine days then you will hear he himself call to go out, and when you hear him call you must not keep him back at all that will make him cross. So I humbly beg you Doctor please to let him out, that countrymen may try with him a little, Sir because they fully understand what is his sickness and in they country it takes only three months to get better and since he is here this now twelve months, so please Doctor let him out let me try with him. They are Crumanty nation nobody don't understand ways excepting to their own country people."

Two Probable Cases of Trichinosis.

Dr. C. W. Wooldridge reports the following cases in the Boston *Medical and Surgical Journal*. He was called to see a man suffering from fever, and general sense of discomfort. The tissue about the eyes was greatly swollen, while a general puffiness seemed to be spreading over the face. There was no pain or inflammation, and no symptoms by which to locate the seat of the trouble. To make the matter more peculiar, a young man, aged 18, residing in the same house, was suffering from exactly the same symptoms, with the only difference that they were a few hours later in their development. He prescribed a little cream of tartar as a safe eliminatory, and awaited developments. The next day the fever was about the same, the swelling had become more general, involving the face and neck, while the hands and arms also showed some puffiness. There was a painful sensation over the stomach, and a diarrhœa, out of all proportion to the medicine given, had set in. On the fourth day the swelling had begun to diminish; but the fever and diarrhœa continued. By this time their complaints of muscular pain were much more decided. Trichinæ now suggested itself. They admitted having eaten a meal of new ham, several days before. The ham had, subsequently, been cooked and eaten, and no trace of it, or of the hog from which it was taken, could be found. After ten or twelve days there was a gradual improvement, but long after all actual disease seemed to have ceased, they were nearly helpless, and two months afterward they were but beginning, in a feeble way, to try to do some work. Twenty-two days after the beginning of the sickness a small piece of the deltoid muscle was removed, and subjected to microscopical examination for trichinæ, with negative results. The Doctor believes that mild cases of trichinosis occur much more frequently than they are recognized. The cause is found everywhere, and there is no practical way in which it can be detected and avoided.

New Treatment for Chordee.

M. Combillard recommends, in *C. Courrier Médical*, to calm the pain induced in gonorrhœa, by nocturnal erections and chordee, injections containing bromide of potassium.

These injections are not, as a rule, in any degree irritating; they may be made four times daily, the last just before bedtime. The liquid should be allowed to remain one or two minutes in the urethra, in order to have the desired effect. The following is the most convenient formula:—

℞.	Potass. bromid.,	ʒ iss	
	Tr. opii,	ʒ ss	
	Glycerinæ,	ʒ iij	
	Aquæ,	℥ v.	M.

In fifteen out of eighteen cases there was rapid diminution, or complete suppression of the erections. Bromide of potash gives these happy results, undoubtedly, owing to its anæsthetic influence on certain mucous membranes in moderating their reflex excitability.

Gallo-Roman Remains.

In 1881 Dr. Habran presented to the Societé Médicale, of Rheims, bones collected from one tomb in the ancient Gallo-Roman cemetery, in the Faubourg de Laon, at Rheims.

These bones presented exostoses at the sternal extremity of the clavicle, and the inferior end of right ulna, junction of the dorsal vertebræ, and finally, ulcerations of the teeth, analogous to those described by M. Parrott in syphilitic children.

M. Habran is of opinion that this ancient inhabitant of Rheims was undoubtedly syphilitic, as proven by the traces left by the disease on the bones.

Resection of a Portion of the Stomach.

The operations of Billroth and Wolfler on the stomach have attracted considerable attention to the surgical affections of this organ (fibrous tumors, foreign bodies, etc.) and a number of other surgeons, among whom may be named Péan, Langenbeck, Rydger and Forelli, have opened the stomach with the scalpel.

The following observation by M. Cavazzini in *Gaceta Medica Provincie Venete*, 22d year is interesting, and has the merit of priority, as the operation was performed in 1874.

A woman, 27 years of age, suffered for over a year from pain in the epigastric region, with vomiting. Directly over the stomach, seemingly in the abdominal parietes, but not adherent to the skin, was discovered an indurated mass, from three to four centimeters in diameter. It appeared to be a fibro-cartilaginous body situated in the abdominal parietes, behind the fascia superficialis, in front of the peritoneum.

As irritating interstitial injections and other forms of treatment remained without effect, and the patient was sinking, it was decided to extirpate the tumor.

During the operation it was found that the tumor reached the walls of the stomach, rendering it necessary to penetrate the organ in order to remove it completely. Sutures were applied, but on the tenth day some of the contents of the stomach escaped at the wound; however, notwithstanding a slight erysipelatous attack about the opening, the patient entirely recovered in about two months.

The patient died of consumption five years later, and at the autopsy the fundus was found drawn upward and toward the left, under the diaphragm. The pylorus was adherent to the parietal peritoneum. Cicatrization of the wound was complete.

Puerperal Zymosis.

In the *British Medical Journal*, Dr. W. Barrett Roué says, "A very painful case has, within the last few days, come under my notice, which illustrates many of the points ably laid down by Dr. Braxton Hicks, in the *Journal* of March 25th. Mrs. B., a lady aged 26, passed safely through her second confinement. For several days all went well; then, all of a sudden, without any apparent cause, her temperature began to rise, and was soon between 104° and 105°. An examination of the sanitary condition of the house was made, with the result of finding sewer gas pouring up from the sink in the scullery, almost sufficient to blow out a candle held over it. The next evening I was sent for in great haste. I found her screaming at the top of her voice, and so violent it was as much as several attendants could do to control her movements, by force; she was suffering from an attack of acute mania. By means of chloroform and hypodermic injections, she was quieted, when typhoid fever was diagnosed, the spots on the abdomen being characteristic. The delirium lasted eighteen hours, after which the patient became conscious and took nutriment well; but such was the frightful exhaustion, caused by her condition, as described above, that she sank slowly and eventually died, in spite of every care and attention bestowed upon her. Surely, it is time the law took cognizance of cases like this. Something should be done in the way of compelling landlords and builders to produce a certificate from a surveyor or other competent person, to the effect that their property is properly drained, previously to a new tenant going in.

Intertrigo in Young Children.

M. Klamm recommends the following powder as very effective in all forms of intertrigo in infants:—

℞.	Magnes. calcin.,	℥ ij	
	Talc. powder,	℥ iv	
	Acid. salicylic pulv.,	℥ ss.	M.

All the ingredients, particularly the magnesia, should be reduced to very fine powder. Salicylic acid may often be advantageously replaced by boracic acid.

This powder has also often been employed with very great success against the various forms of erythema and eczema, which are developed about the anus in young children, under the influence of diarrhœa. It is of great benefit, too, in seborrhœa of the scalp; in ulcers of the lower limbs, and finally, as an application to vesicated surfaces.

Diseases of the Ankle Joint.

At a recent meeting of the Medico-Chirurgical Society, of Edinburg (Edinburg *Medical Journal*), Mr. Joseph Bell, showed a patient who had suffered for some years from disease of the ankle joint, but whose foot he had been enabled to save by means of a free antiseptic incision. He thought it was rare that good results were seen in cases of joint disease of long standing. This patient, a boy of 19, had suffered from pain in the ankle for nearly five years. For the last two years the pain had been intense. He was unable to put

his weight on it, and sometimes was even unable to sleep at night. The disease was entirely confined to the ankle joint. It was decided to make a free incision and thorough drainage, under antiseptic precautions. The incision was accordingly made. An ounce and a half of pus was let out, and a drainage tube passed into the joint. The symptoms were at once greatly relieved. The patient remained in the hospital about two months, and was sent out with the wound healed and a starch bandage on, to keep the joint quiet. This was now off, and the movements at the ankle were almost perfect and there was no evidence of disease. He will go about for some time on crutches.

Incontinence of Urine—Circumcision—Recovery.

Dr. Wm. Muir reports the following in the Glasgow *Medical Journal*, April, 1882: "A boy aged twelve was admitted into the Royal Infirmary, suffering from incontinence. It commenced two years before, by pain on micturating, and shortly afterwards the urine came away of its own accord. No history of injury or any other disease. Urine quite normal. Was examined repeatedly for stone, and belladonna, iron, and Easton's syrup were tried in turn, but all of no avail. It was noticed that the foreskin was unusually long and a little inflamed. Circumcision was performed. The most satisfactory result ensued, and in two months the patient was discharged quite cured."

Extirpation of a Pulmonary Hernia.

M. De Los Mozos reports an interesting case in the *Revista de medicinia y cirurgia practicas.* A young man, 17 years of age, received, in a fight, a large stab wound, three centimeters in width, between the fifth and sixth ribs, on the left side, and through it protruded a portion of the lung as large as a small orange.

The patient was pale, almost in a state of collapse, with filiform pulse, and suffered from incessant coughing, with sanguinolent expectoration; he could lie only on the right side. After forty-eight hours, however, his condition improved wonderfully, and remained so during the following days. As the portion of lung protruding, could not be reduced, the physician in charge fearing mortification, extirpated it entirely, applying the actual cautery to arrest hemorrhage.

The patient made an excellent recovery, the wound cicatrized well, and no deformation of the thoracic parietes or alteration in the respiration ensued.

Correspondence.

Puerperal Albuminuria.

Ed. Med. and Surg. Reporter:—

Under the above head Dr. Millikin reported a case of unusual interest in the Reporter for April 15th. I have notes of a case in some respects similar, which I venture to give, since the subject, although one of great interest, has not received the attention its importance demands at the hands of authors and teachers.

About the 1st of November, 1879, I was called to see Mrs. D., a young woman 21 years of age, about four months advanced in her first pregnancy, and with a history of good health. Never had had rheumatism, but had scarlet fever when quite young, during which period she was salivated severely. For some time after her recovery and during convalescence she was slightly dropsical.

I was called on account of the presence of general anasarca, which had begun to manifest itself some weeks previous. On my first visit I found the patient unable to wear a shoe, so great was the swelling of the feet. She complained of headache continuously, and at times her sight was defective. Of the source of the trouble there could be no question it was due to one of two possible agencies, either Bright's disease or the albuminuria of pregnancy. The urine on examination produced at least 75 per cent. of albumen. I sent a specimen of the urine to Dr. French, of Davenport, who examined it under the microscope, and found it to contain many tube-casts. The scarlet fever history rendered the trouble a little uncertain in its termination, for if the pregnancy were simply the existing cause of a malady that had been quiescent for some time, the probable ending of the case must be death, and that soon.

The treatment given at first was iron. The bowels were free and regular. I prescribed tincture of the chloride in full doses. It had the effect of preventing the increase of the anasarca, but that was all. There was no diminution of the swelling nor was the headache lessened. She was given the compound jalap powder, until free catharsis was produced. This lessened the anasarca, but did not remove any considerable amount of it, nor did it relieve the headache. By this time the case had assumed such proportions that it was equaled only by the number and variety of remedies used to relieve the patient. About the middle of January it became evident that unless some means to prevent the anasarca, be secured, premature labor must be induced. As a dernier resort, I prescribed fluid extract of jaborandi in half drachm up to drachm doses. In less than two weeks the headache was almost all gone and the anasarca greatly diminished. The patient continued to take the jaborandi until confinement, which occurred March 14th, when, after a labor lasting 30 hours, she gave birth to a large, healthy child. At no time did she show the least sign of a convulsion. In a few days after confinement all the anasarca disappeared and the patient has enjoyed good health ever since. There has been no albumen in the urine since.

I have not had an opportunity since then to try the remedy in a similar case. During the fall and winter of 1881-82, I gave the remedy to a patient who was suffering from Bright's disease. Before he had taken enough of it to test its virtues, he got drunk, and while enjoying a week's debauch was taken with convulsions and died.

Possibly others have used jaborandi, and with what success many of the profession, I doubt not, would be pleased to hear through the REPORTER.

Le Claire, Iowa. J. A. DE ARMOND, M.D.

Pruritus Ani.

ED. MED. AND SURG. REPORTER:—

This affection, though not very frequently met with, is one of the most obstinate to cure, or palliate. Authorities speak of it occasionally, and refer to it as a nervous disease. I have used most everything recommended, and until recently failed to either palliate or cure. The following formula has given general satisfaction, not only as a palliative, but a cure:—

℞. Flour of sulphur, ℥j
Petroleum mass, ℥j. M.
Make ointment.
Sig.—Apply once daily.

The remedy would indicate the disease to be of a parasitic origin. The sulphur combined with cosmoline, vaseline, or lard, does not give the same results. I think much of the petroleum mass in all diseases characterized by itching. Although it has been abused by being extensively advertised as a quack remedy, it has many valuable properties as a therapeutic agent.

The above formula never fails to cure dandruff of the scalp or pruritus on any of the hairy portions of the body. M. MILTON, M.D.

Bradford, Pa.

Jaborandi.

ED. MED. AND SURG. REPORTER:—

The first number of the MEDICAL AND SURGICAL REPORTER for April is at hand.

I write because I am heartily in accord with the able editorial on "Jaborandi," and wish to give a few notes of a case in which jaborandi was used with marked benefit.

January 10th, 1882, was called to see a child, five years of age, who was suffering with scarlatina. In a few hours after the onset of the disease the child became violently delirious; temperature 106° F.; pulse 160–180. The eruption came out the next day and was very profuse. Under ergot, bromides, calabar bean, etc., cerebral symptoms gradually subsided, and on the fourth day the fever began to subside, and the child became rational. However, the urine remained scanty and highly albuminous, notwithstanding the usual means for its relief—as purgatives, counter-irritation in lumbar region, steam baths, etc.—were used freely and early. During the third week there was suppression of urine for three days, with excessive vomiting, dropsy, etc., though there was no coma. Elaterium was used several times, and the watery discharges gave temporary relief. Upon the morning of the fourth day I gave half a drachm of fl. ext. jaborandi, and within ten minutes diaphoresis commenced and soon became excessive, the vomiting, etc., disappeared, and within four hours he voided half an ounce of urine. No more jaborandi was given, as the diaphoresis continued nearly all day, and before midnight he had passed several ounces of urine. This case recovered without further noteworthy symptoms. It is true that the elaterium relieved him, but the kidneys remained inactive, while, after the profuse diaphoresis, caused by a single large dose (for a child) of jaborandi, the kidneys soon resumed their function.

It may be that I over-value jaborandi, but it is certain that, in a similar case, I should use it again, and also think it might have relieved the delirium of the first three days as well.

Chicago, Ill. E. C. HELM, M.D.

Puerperal Convulsions.

ED. MED. AND SURG. REPORTER:—

In 1859 I read, in an article in a Medical Journal published in Columbus, Ohio, that the tr. of stramonium would cure puerperal convulsions by giving half an ounce at a time. It was also claimed that it would cure any other convulsions.

Not long afterward there was a case occurred near my office, in a female, about 55 years old. After five or six days her physician gave her up as a hopeless case. One evening, just as I was ready to make a visit in the country, her niece came to me and asked me to come and see her aunt, and try to do something to relieve her. I filled a half-ounce vial with the tr. of stramonium and directed a teaspoonful every hour till relieved. In about four hours I returned and found the vial empty. I was told that she had no convulsions after the last dose was given.

(Now I would not recommend the above heroic treatment in every case of convulsions; yet I would not hesitate to give the above treatment after all other legitimate treatment had failed.)

Her pulse was nearly normal, her breathing easy, and the next day consciousness returned. She never had any convulsion afterward, to my knowledge. E. A. OPPELT, M.D.

Loogootee, Ind.

Burns.

ED. MED. AND SURG. REPORTER:—

A burn with oil is the worst kind of a burn. Steam makes a very bad burn. To distinguish a burn from a scald, look closely and observe the hair. If the hair is entire, it is a scald; if it is a burn, the end or the whole of the hair will be minus. A large slight burn is more dangerous than a small bad burn. A burn over the abdomen is more dangerous than one over the thorax. When a burn covers over one-third of the body death may be expected; especially if it is on the abdomen. There are three stages of burns. 1st. Depression; 2d. Congestion; 3d. Reaction. Depression and congestion sometimes affect the brain and cause death by effusion.

Burns over the abdomen cause inflammation of the kidneys, which produces retention of urine. In such cases see to it that the patient urinates frequently. Cream of tartar in water should be given as a drink. For the intense itching caused by burns, nothing is better than liquor potassii arsenitis. In treating a burn, bring about reaction. Give ammonia and brandy by stomach or rectum. Keep the air from the burn and thus lessen the pain. If necessary, the child, or whoever is burned, may be placed in a tub of tepid water, and so exclude air till you are ready to dress the wound. Dry bicarbonate of soda, put on thickly and bandaged on, is a very good dressing. Some prefer it in form of a saturated solution. Glycerine, olive oil and vaseline are good dressings. But to exclude the air is of so much moment, that no time should be lost, and if no better substance be at hand, do up the burn in plenty of dry flour. Unless there is a copious discharge, burns should not often be dressed. If there is any considerable rise of temperature, tr. aconite should be given. If suppuration takes place, support patient by a generous diet, and give quinine and iron.

East Madison, Me. A. E. Farnham, M.D.

Revaccination.

Ed. Med. and Surg. Reporter:—

In the number of the Medical and Surgical Reporter for December 3d, 1881, I asked several questions on vaccination. Several answers have been received, but the answers to the most important question have been so conflicting that I will restate it:—

"Are there persons, *never having* had any vaccine marks or scars, who are insusceptible to the action of vaccine virus, and if so, are they exempt from variola." I have been vaccinated about thirty times the past year, usually using bovine virus on ivory points, but have taken the fresh lymph direct from a child's arm, and from the heifer. The operation has been performed on both arms and one leg, and by several physicians, using reliable virus. I will give a synopsis of the answers I have received:—

Dr. T. H. Manley, of New York City, in the Medical and Surgical Reporter of December 17th, 1881, writes, "In *no one* is there such a thing as insusceptibility to the action of good vaccine virus properly inoculated. * * * * Possibly it may be that those whose symptoms are antagonistic to vaccination may not so *readily* acquire smallpox; but * * * when the disease does attack them it does so in all its malignity."

In the same issue of your journal Dr. J. L. Suesserott, of the "Jenner Vaccine Farm," of Chambersburg, Pa., writes:—

"There are persons who resist the influence of vaccination, and also of smallpox after repeated vaccinations, but it is altogether probable that there have been periods when, if properly exposed, they would have taken either disease."

Dr. J. M. Dixon, of Chicago Vaccine Farm, writes: "I am confident you are *not* susceptible to the vaccine disease, or smallpox, and think you need have no anxiety whatever."

E. M. S., of Providence, R. I., in Medical and Surgical Reporter, writes: "I know that some persons are *temporarily insusceptible* to the effects of vaccine virus."

Dr. T. A. Worrall, of Northeast, Md., in Medical and Surgical Reporter, of Jan. 14, 1882, supports the views of E. M. S.

These physicians, from an extensive and varied experience, are eminently qualified to speak, but inasmuch as there is not entire harmony between them, I would greatly desire to learn the views of others, and of the editor. E. C. Helm, M.D.

Chicago, Ill.

News and Miscellany.

Photographic Group of the International Medical Congress.

We notice in the *Lancet* that Mr. Barraud, of Gloucester-place, Portman square, has published a photographic group of many of the members of the late International Medical Congress. It includes 684 figures, who are grouped in an effective manner. The portraits are remarkably good, and the picture is a valuable memorial of the wonderful meeting of last August. We cannot help referring to the striking success with which Mr. Barraud has caught the likenesses of Prof. Charcot, Dr. Donders, Sir Thos. Watson, Prof. Huxley, Prof. Pasteur, Prof. Virchow, Prof. Esmarch, Dr. Bigelow, Mr. Spencer Wells, Mr. Luther Holden, Dr. Billings, Sir. Wm. MacCormac, Mr. Wood, Mr. Marcus Beck, Dr. Lancereaux, Sir Erasmus Wilson, Dr. West, and Dr. Wilson Fox. Mr. Barraud is to be heartily congratulated on the signal success of his picture, which is one of the largest and most interesting groups we have ever seen.

Consultations with Homœopaths.

The following is an extract from an article by Professor Palmer, in the *North American Review* for March:—

"The object of a medical consultation is to benefit the patient, to secure for him, by exchange of opinions and by mutual agreement, the best course of treatment. It is too evident to require to be stated, that there can be no agreement between a regular physician having any established professional views, and a sincere homœopathist. No benefit can arise to the patient from the practical disagreement which would be inevitable. The conscientious believer in the universal principle of *similia similibus* could not consent to the use of any remedy not selected in accordance with that law. One believing in the efficacy of infinitesimals and in the injurious effects of medicines in crude forms and sensible doses, could not consent, with any regard to the supposed interests of his patient, to the administration of the larger doses. If, for the purpose of securing patronage, the homœopathist pretends to a superior system in which he does not believe, and to a better practice which he does not follow, he is a charlatan and a pretender, unworthy of confidence or honorable associations. If a regular physician, for the sake of a consultation fee, or for the purpose of obtaining popular

favor, sacrifices his convictions, relinquishes measures in which he has confidence, and consents to a practice he is sure is useless, he may be a fitting person for such consultations, but he is not an honorable member of an honorable profession. If between an honest homœopathist and an equally honest regular physician there can be no agreement and coöperation in the treatment of a case, consultations are certainly useless, and no opinions need be expressed respecting consultations between parties one or both of whom are insincere. Should the homœopathist abandon his system, or the regular physician embrace it, there may be harmony and agreement, but until then consistency and honor, no less than proper professional feelings, will forbid the unnatural alliance."

American Medical Association.

The only railroads that have granted reduced rates for the thirty-third session are those between Chicago and St. Paul. The fare will be $12.50, or half fare from Chicago to St. Paul and return; granted only to those who exhibit their credentials, or an order from this office.

WILLIAM B. ATKINSON, M.D., *Secretary*,
1400 Pine Street, southwest cor. Broad.

The Secretary of the Surgical Section of the American Medical Association has the following progress to report in regard to papers for the next meeting: Prof. A. C. Post, "Lupus Exedens of Face;" Dr. J. R. Weist, "Elastic Tension in the Management of Cases of Delayed Separation of Ligature;" Dr. Henry A. Martin, "Advances in Conservative Surgery of the Joints;" Dr. Carl Seiler, "Some Remarks upon Electricity in Surgery;" W. M. Fuqua, "Subperitoneal Surgery;" Dr. A. Van Derveer, "Cleft of Hard Palate;" Dr. Oscar J. Coskery, "Modification of Plaster Splint;" Dr. G. W. Nesbitt, "Ununited Fracture of Femur Treated by Exercise;" Dr. John E. Link, "Alcohol as an Anæsthetic;" Dr. Wm. Hill, "Laparotomy;" Dr. Ephraim Cutter, "Bi fracture of Patella, Partial Bony Union after Eight Years." Dr. Wm. Stewart, "Fracture of Elbow-Joint." Drs. J. W. Dora, Joseph H. Warren, Henry O. Marcy, Edward Borck and B. H. Riggs promise papers, titles not received. The Secretary, owing to the death of the chairman, will read a paper on "Excision of Portions of the Alimentary Canal Covered with Peritoneum," as the Address on Surgery. Gentlemen wishing to read papers will please notify the Secretary of the Section. WILLIAM A. BYRD, M D.
407 *Jersey Street, Quincy, Illinois.*

Camden County Medical Society.

The thirty-sixth annual meeting of the Camden County Medical Society was held at the West Jersey Hotel on May 9th, with a large attendance. The proceedings were of much interest.

The report of Dr. Snowden, of the Standing Committee, on the prevalent diseases of the county during the year, indicated that malarial, typhoid and other specific fevers have been unusually prevalent, although the mortality has been light.

Dr. Benjamin discussed the importance of a thorough medical education, and the result was the adoption of the following:—

Resolved, That we, members of the Camden County Medical Society, will give our encouragement to those colleges which have advanced the standard of medical education. It was also

Resolved, That the greatest good to medical science, to the members of the medical profession, and to the public, is maintained by adhering to the code of medical ethics of the American Medical Association, relative to consultations.

The following officers were elected, and committees appointed for the year: President, E. L. B. Godfrey, M.D.; Vice President, John R. Haney, M.D.; Secretary, H. Genet Taylor, M.D.; Treasurer, Isaac B. Mulford, M.D. Standing Committee, Drs. Snowden, Branin, Shivers, Mulford and Smith.

Censors, Drs. Jennings, Schenck, Snowden and Branin.

Delegates were appointed as follows: To American Medical Association, meeting at St. Paul, Minn., in June, Drs. Schenck, Benjamin, Stevenson and Branin.

New Jersey Medical Society, meeting at Asbury Park, May 23d and 24th, Drs. H. Genet Taylor, Pancoast, White, Jennings, Smith and Wroth.

After dinner some of the gentlemen made remarks as follows: Dr. J. F. Garrison, on the "Philosophy of Darwin;" Dr. Ridge, on "Ancient Medicine;" Dr. Woolston, on "Medical Efforts of New Jersey During the Revolution;" Dr. Benjamin, on "American Surgery;" Dr. Snowden, on the "New Jersey Medical Society," and Dr. Schenck, on the "Medical History of Camden County."

State Hospital for Women and Infants.

We have received the Eighth Annual Report of the State Hospital for Women and Infants. From this report we note that this is the only institution in Pennsylvania organized and maintained for the express purpose of affording shelter to unmarried women. During 1881 there occurred in the institution 81 confinements. The average period patients remained in the hospital was 45 days. The average cost of board, including rent, was $4.90 per week. Contributions and bequests are solicited, and since the purpose is a worthy one, they ought to be forthcoming.

Typhoid Fever.

An outbreak of typhoid fever of a serious kind, in the Leicester Infirmary, has been carefully investigated, with the result, it is said, of pretty conclusively tracing it to the milk supplied to the institution.

College for Medical Practitioners.

A college has been inaugurated in St. Louis, for the purpose of teaching medical practitioners, by practical instruction, the branches of medicine and Surgery. The Dean of the College is Dr. Thomas F. Rumbold.

Medical College of Utah.

The Medical College of Utah, located at Morgan City, Utah Ty., has issued its third annual announcement for the session of 1882.

Lancaster County Medical Society.

The Lancaster County and City Medical Society have commenced the publication of their Transactions in a pamphlet, of about forty pages. Its management is in the hands of a publication committee.

College of Physicians and Surgeons of Iowa.

A circular has been received announcing the organization of the College of Physicians and Surgeons of Iowa at Des Moines. The college year will begin on the second Tuesday of October, 1882, and will include twenty weeks of instruction. J. A. Blanchard, M.D., of Des Moines, is Dean and J. F. Kennedy, M.D., of the same city, is Secretary of the Faculty.

An Anæsthetic Mixture.

The *Wien. Med. Zeit.* says that the Vienna mixture, under the use of which 8000 operations have been performed without a single accident, consists of three parts of ether and one of chloroform; and Billroth's favorite mixture is composed of three parts of ether, one of chloroform and one of alcohol.

Skimmed Milk.

The daily papers of May 2d state that a man in Troy, New York, who has been living on skimmed milk since January 13th, will continue his restricted diet for some weeks longer. He never felt better or stronger. His face is round and rosy and his weight 214½ pounds. He is apparently in good condition and experiences no craving for solid food.

Items.

—According to Sir Henry Thompson, soups are far too lightly esteemed by most classes. They are too often regarded as a mere prelude to a meal, to be swallowed hastily or disregarded altogether.

OBITUARY NOTICES.

JAMES R. WOOD, M.D.

Professor James Rushmore Wood, M.D., LL.D., of New York, died May 5th, at his residence in New York City, of pneumonia, aged 65 years. Dr. Wood's early opportunities for intellectual training were limited, owing to the very moderate circumstances of his parents, but with the irrepressible energy and ambition of true genius, he availed himself to the utmost of his meagre facilities, and finally graduated from the Castleton (Vt). Medical College, in 1846. He was at once appointed Demonstrator of Anatomy in his alma mater. He removed to New York City in 1847, and became connected with the Bellevue Hospital, and immediately undertook to reform its sanitary condition, in which he was ably seconded by Drs. Wilson and Drake, and Mr. Moses Franklin, then President of the Board of Aldermen. Within three years after the inauguration of this reform the statistics of the Hospital showed a reduction in mortality equivalent to the saving of 600 lives annually.

In October, 1856, Dr. Wood established the Saturday surgical clinics, which soon became very popular with both students and practitioners alike. From this small beginning was ultimately developed the Medical College, which was established in 1861, through his efforts, in connection with those of other leading physicians and surgeons. To this college his museum is given. He has been connected with the college from its inception, an active Professor of Operative Surgery until 1868, when he resigned, and since that in other relations. His Saturday clinics, which have contributed in no small degree to give prestige to the college, had been continued up to the time of his fatal illness. One of Dr. Wood's most important contributions to operative surgery resulted from his vast clinical experience at Bellevue Hospital. This was the first successful demonstration of the fact of the reproduction of extirpated bone, by a new growth from the periosteum.

During the great fever epidemic, when the grounds about the hospital were crowded with tents containing the afflicted, Dr. Wood's services were so highly appreciated that the Almshouse Commissioners offered him a special remuneration. This, in a monetary way, he declined, but asked and received permission to make all autopsies ordered by them.

While at Bellevue Hospital, Dr. Wood conceived the idea of the "Dissecting Bill," so called, by means of which a want long felt by medical schools was partially supplied, the law providing that all unclaimed bodies of vagrants, paupers, etc., shall be given to such institutions, for the purposes of the dissecting-room. Previous to the passage of this statute, bodies for dissecting purposes were obtained by raids made by students or professional "body-snatchers," from the Potter's Field, or such other burial-places as could be successfully raided.

His operations for calculi were numbered by hundreds. Indeed, no living surgeon has a record of so many capital operations with so little loss of life. His triumphs in surgery, joined to a genial disposition and winning address, resulted in a large practice and accumulation of a considerable fortune.

As a medical writer, Dr. Wood has not been prolific, his works consisting in the main of papers on surgical subjects read before various societies, such as his essays on the "Growth of Bone;" on the "Removal of the Entire Lower Jaw;" on "Ligature of the External Iliac Artery;" "Spontaneous Dislocation of the Head of the Femur," and the "Early History of Ligature of the Primitive Carotid Artery," all of which have been published, and are authorities in their special fields. He was a member of the New York Academy of Medicine, the American Medical Association, the New York Pathological Society, of which he was twice president; the New York Medical and Surgical Society, the New York Society for the Relief of the Widows and Orphans

of Medical Men, and the *Medical Journal* Association. He was also a corresponding member of the Historical Society of Yale College. As a clinical instructor, Dr. Wood was highly esteemed, and in this capacity he may be said to have been the pioneer of the new method—that which prefers the study of the patient to that of the text-book, and experience with disease to description in the lecture-room—a method whose traditions have become the feature of the college he founded. As a lecturer he was terse and vigorous, as a clinical Professor clear and exact.

JOHN T. HODGEN, M. D.

Professor John T. Hodgen, the distinguished medical teacher of St. Louis, died, after a very short illness, on April 29th. His death was the result of a rather singular cause. While giving expert testimony in court, he was compelled to ask to be excused on account of intense suffering. When he reached home, he was barely able to crawl up stairs on his hands and knees. Lingering for twenty-four hours in intense pain, he died. A post-mortem revealed erosion and perforation of the gall-bladder, with peritonitis. Professor Hodgen was a typically self made western gentleman. Born among the prairies of Illinois, and denied, on account of parental poverty, the advantages of early education, he was compelled to shift for himself. When twenty years old he began the study of medicine, and upon graduation, was appointed Prosector to the Chair of Surgery, under Professor McDowell. In 1850, he was made Demonstrator of Anatomy in the Missouri Medical College, and in 1852, Professor of the same branch. In 1861, he was elected to fill the same chair in the St. Louis Medical College. In 1872 he was elected Professor of Clinical and Military Surgery, which position he held at the time of his death. Dr. Hodgen was a great surgeon; he was especially blessed with the power of meeting emergencies. As a man, he was silent, thoughtful, dignified and impressive. His was a life to be imitated by all young physicians; enemies he had not, while all who ever met him were ever after warm friends. Want of space forbids a more extended notice, though much more could be said of this truly good man. Dr. Hodgen presided over the last meeting of the American Medical Association, at Richmond.

ERSKINE MASON, M.D.,

One of the attending surgeons of the Roosevelt Hospital, died on the 13th of April, at the age of 45.

At the opening of the Hospital, in 1871, Dr. Mason was appointed an attending surgeon, and he continued in that connection until his death, being then one of the two to whom the surgical administration of the hospital was intrusted.

Devoted to his profession from the commencement of his career, and with the advantages of education and experience afforded in this city, he had at the time of his appointment a high and honorable standing as a surgeon, and during the years which have elapsed, by his assiduous attention to the duties of his position, by performance of his full share of all labor, by many successful and difficult operations, and by the courtesy and kindness of his intercourse with all, he has added as well to his own reputation as a learned and able surgeon, as to that of the hospital with which he was connected.

DR. JOHN E. GILBERT.

At a meeting of the Medical Association and other physicians, held at the office of Dr. Robert Horner, Gettysburg, to take action on the death of Dr. John E. Gilbert, Dr. A. Nod, of Bonneauville, was called to the chair, and Dr. J. W. C. O'Neal appointed Secretary.

Drs. Charles Horner, James D. Weddelle and Robert Horner were appointed a committee, who reported the following preamble and resolutions, which were unanimously adopted.

WHEREAS, In the providence of God, death has once more entered the ranks of the Medical Society, and cut down Dr. John E. Gilbert, one of the youngest and most prorising members of the Association, it is therefore

Resolved, That we feel a deep sorrow in the death of our late associate, one whose genial manners, laudable ambition in the practice of his profession, and whose faithful and honorable attention to duty not only endeared him to the members of this Society, but likewise to the community.

Resolved, That as a mark of respect we will attend in a body the funeral, which takes place on Sunday, April 23d. at three o'clock P. M.

Resolved, That the Secretary forward a copy of these proceedings to the family, to the Gettysburg papers, and THE MEDICAL AND SURGICAL REPORTER, of Philadelphia, and that they be recorded in the minutes of the Adams County Medical Association.

QUERIES AND REPLIES.

E. S. R., M.D.—For *Hyperidrosis of the Palms* we would recommend frequently washing the palms with a saturated aqueous solution of boracic acid.

J. W. C., Ala.—You can obtain the article you desire, pure, from any *reliable* drug house.

MARRIAGES.

BRITTON—KIRBY.—On Thursday, April 27th, 1882, in St. Paul's Church, Camden, N. J., by the Rector, Rev. J F. Garrison, D.D., Dr. Charles P. Britton, of Trenton, N. J., and Katherine G., daughter of John Kirby, M.D.

CHEESMAN—CUYLER.—In Brooklyn, Thursday, April 27th, 1882, by Rev Theodore L Cuyler, Dr. Wm. S. Cheesman, of Auburn, N. Y., and Miss Mary E. M. Cuyler, only daughter of the officiating clergyman.

CHANCE—MICKLEY.—At the residence of the bride's parents, April 20th, 1882, by Rev. E. J. Fogel, Dr. H. M. Chance, of Philadelphia, and Miss Lillie E., daughter of Edwin Mickley, Esq., of Hokendauqua. Pa.

COVERT—QUICK.—By Rev. G. M. Potter, April 20th. S. J. Covert, M.D., of Evansburg, Pa., and Miss Ellen M. Quick, of Perrysville, O.

DEATHS.

PERHAM.—On Thursday, April 27th, Daniel W. Perham, M.D., aged 29 years.

PIERSOL.—Suddenly, on the 27th of April, Jeremiah M. Piersol, M D., in the fifty-sixth year of his age.

STUDDIFORD.—On Saturday, April 15th, at Lambertville, N. J., Theodore H. Studdiford, M.D.

YOST.—April 12th, 1882, at Logansville, York, Co., Pa., Spencer Wells, infant son of Dr. George P. and Olivia V. Yost, aged 8 months and 27 days.

1180-eowtf

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

Lecture.

PURULENT INTERLOBAR PLEURISY; DISCHARGE THROUGH THE BRONCHIAL TUBES.

Delivered at La Charité Hospital,

BY M. HARDY, M.D.,

Professor of Clinical Medicine of the Paris Faculty.

Gentlemen:—My lecture to-day will be devoted to the consideration of the diagnosis of the malady of the patient in No. 17, St. Charles' ward.

I will first read the observation in full, as presented by my chef de clinique, M. Josias. The patient is a tailor, 44 years of age, who entered M. Hardy's service on February 20th, 1882. His family antecedents are good, his father dying at 80 years of age, from the effects of an accident, and his mother at 71, of a tumor in the axilla. Two sisters died very young, and he has four sisters and a brother living, all in good health.

Personal antecedents—no scrofulous accidents during childhood; at five years of age, smallpox: at twenty, gonorrhœa and chancre, which lasted fifteen days, and was not accompanied by bubo, syphilides or mucous patches. When 27 years of age he had an eruption of chocolate-colored spots on the breast; they were as large as a dime piece, not at all itchy, of an oily aspect, and persisted five or six years (pityriasis versicolor).

At the same period, while in Italy, the patient had a series of febrile attacks, concerning which he can furnish but incomplete data; they supervened twice monthly for two months, and consisted in a sensation of heat with profuse sweating and dyspnœa.

When 38 years of age he suffered from slight pains in both feet, with swelling of the toe joints, and since he has had similar pains every winter.

In October, 1880, he had attacks of dyspnœa, occurring principally at night, for ten days, accompanied with a painful stitch in the præcordial region, the slightest movement inducing dyspnœa. There was also considerable cough, with purulent expectoration, which continued, but without hæmoptysis, up to March, 1881.

On February 4th, 1882, pain supervened in the right side, without chill or dyspnœa, and since then he has been obliged to remain in bed, any attempt at standing proving impossible. There was no cough or expectoration. On February 18th he suddenly felt a very bitter liquid mount from the chest to the throat, and immediately vomited about a basinful of greenish, purulent liquid, of very fetid smell. For three hours after he was harassed with continual coughing, accompanied by excessive purulent expectoration, and this has troubled him since almost incessantly, up to the time he entered the hospital.

At present, although a man of apparently strong constitution, he seems almost worn out; the body covered with sweat, and the eyes somewhat sunken. Respiration is frequent and noisy; the cough almost incessant, but soft and not painful. Expectoration is abundant, frothy, slightly purulent, but not at all fetid, as it was yesterday.

Inspection shows no appreciable dilatation, or œdema of the thoracic parietes. Sonority is normal on both sides of the chest anteriorly; the vesicular murmur is somewhat obscure, and re-

placed by rude respiration, without râles, on the right side; on the left it is normal. Posteriorly, vocal fremitus is not as evident as usual low down on the right side, which seems, also, somewhat dilated; there is also diminution of elasticity on percussion over the right apex, and dullness over the lower two-thirds of the same side. On auscultation, there is blowing respiration over the angle of the scapula on the right side posteriorly, with slight friction murmur, and subcrepitant râles lower down.

There is neither egophony nor bronchophony, but amphoric souffle, with metallic tinkling, is heard over the right scapula posteriorly, when the patient coughs. The liver is not hypertrophied, but is somewhat painful when percussed.

February 22d. He rested well during the night, but had an attack of coughing, with considerable expectoration, this morning. Matters expectorated are slightly purulent and do not contain blood. There is now complete dullness over right side posteriorly; amphoric sounds are heard at angle of scapula, but no metallic tinkling. The general condition of the patient is satisfactory; the pulse at 120, the temperature 102°.

In the evening of the same day the physical signs were found to be about the same; the friction murmur being more evident, and heard over a greater extent of surface. There was considerable purulent non-fetid expectoration during the day.

On February 23d expectoration was more abundant and somewhat fetid; the fever continued with sweating. Over the lower third of the right side posteriorly there was still marked dullness with friction murmur and subcrepitant râles. There is amphoric souffles at the angle of scapula when the patient coughs. The left side is normal.

At 3 P.M. on the 24th he had a sudden discharge of about eight ounces of fetid pus. On February 25th his condition is about the same. There is considerable frothy, muco-purulent expectoration, which, on histological examination, is found to contain leucocytes in great number; very large pavement cells, with large nucleus, a few blood globules, but no elastic fibres. The cough is soft, almost immediately followed by expectoration.

Examination of the chest shows slight œdema of the thoracic parietes on the right side, but no dilatation.

Vocal fremitus remains somewhat obscure at the base of the lung, but dullness is not at all so marked.

Auscultation reveals large, dry bronchial râles under the right clavicle, and posteriorly on the same side sibilant and subcrepitant râles at the base, and friction murmur over the inferior two-thirds of the lung, obscuring the respiratory sounds. At the angle of the scapula the cough has a metallic ring.

Such, then, is the observations in detail, and it will be, I think, evident that the diagnosis presents many difficulties, and can only be established by proper analysis and discussion of the various symptoms presented by our patient.

The first which particularly attracts attention is the sudden and profuse expectoration of a fetid purulent liquid; to this phenomenon the designation vomica has been applied in France. Vomica, or the sudden discharge of pus through the bronchial tubes, was generally attributed by the older authors to the evacuation of a pulmonary abscess, and according to Laennec, such discharge implied the existence of lung cavities, to which, indeed in the English systems of pathology, the term "vomica" has been applied, but such is not the case.

To-day it is generally admitted that a discharge of pus through the bronchial tubes oftenest merely passes through the lung, originating either in the chest or abdomen.

Of all the morbid conditions which may give rise to such a discharge, pleurisy must be placed in the first rank. Pleurisy, in such a case, may be compared to a pleural abscess, rupture of the subjacent serous membrane and lung tissue establishing a communication between the purulent collection and bronchial tubes, permitting evacuation of the liquid.

This is the prominent symptom in the case before us; the sudden expectoration of a considerable quantity of pus after a fit of coughing would seem to point to the existence of empyema.

It must, however, be admitted that almost all the symptoms which usually characterize empyema are wanting, with the exception of the stitch in the side and the febrile reaction. The patient is, it is true, extremely feeble, and cannot support himself in a standing position; he has also some tendency to sweating, but the period of production of the pleurisy remains exceedingly obscure.

If it be really a case of empyema, revealed by the discharge of pus through the bronchial tubes, we are obliged to admit the existence of a communication between the pleural cavity and the exterior; in other words, we should seek for and find all the signs of pneumothorax.

But our patient presents none of the signs which would permit us to affirm the existence of pneumothorax or hydro-pneumothorax, and

what is more, all the symptoms of effusion into the pleura are wanting.

When a pleuritic effusion is discharged through the bronchial tubes we have generally dilatation of one side of the chest, with dullness at the base and exaggerated sonority at the apex of the lung, amphoric sounds, metallic tinkling, etc. The absence of all these symptoms renders the diagnosis difficult and obscure.

We consider that the discharge of pus in this case originates from empyema, but the assertion alone is not sufficient, it remains for us to determine with precision the point where the effusion was developed.

There has been no effusion into the grand pleural cavity, for the stethoscopic and other physical signs of such effusion are wanting. The purulent collection is in effect in the interlobar space. You are aware that pleurisy may be partial and limited to the inferior surface of one lobe.

Adhesions may in this way be formed about the interlobar space, so as to constitute a closed cavity, in which a liquid effusion takes place. While this inflammatory process is going on, the symptoms engendered are obscure, limited generally to slight pain and some slight derangement of the general health.

As the effusion increases the two lobes are compressed, and sometimes become so solidified that the purulent collection may be mistaken, as it was by the earlier authors, for an intra-pulmonary abscess.

In our case the liquid was effused under analogous conditions, finally acquiring such a volume as to compress the lung tissue ; then ulceration and perforation ensued, and the purulent collection was evacuated through the bronchial tubes.

These considerations, gentlemen, are by no means hypothetical ; they are drawn from the consideration of the symptoms presented by our patient. When he first entered the service we found on auscultation metallic tinkling and amphoric sounds with the cough ; these signs permitted us to affirm the existence of a cavity containing air in contact with the lung. At present there is merely a metallic ring to the cough, showing that the cavity which formerly gave rise to metallic tinkling still exists.

If, however, we take into account the conditions necessary for the production of this metallic sound, and the fact that it is heard only when the patient coughs, we are led to believe that the cavity is but of small dimensions.

From all these physical signs we conclude that this is a case of empyema, localized in an interlobar space, and in direct communication with the bronchial tubes, which explains the mixture of air with the purulent expectoration.

If the opening is obstructed, there is, for a time, cessation of the cough and expectoration, which again reappear as soon as the communication is re-established.

I cannot dissimulate how great is our embarrassment when we seek to determine the causes which lead to the development of this form of empyema.

Our patient is an over-worked, poorly nourished tailor, and it would seem that the malady was brought on by cold, and the nature of the liquid influenced by the bad state of the general health.

There is, then, interlobar pleurisy on the right side. But what is the precise location ? Between which lobes is the liquid contained ? This local diagnosis is always extremely difficult, but as we find the metallic ring with the cough and the metallic tinkling at the inferior angle of the scapula, it would seem very probable that the space between the two upper lobes on the right side contained the liquid.

What are the prospects of the case ? I do not hesitate to say, gentlemen, that the prognosis is serious. Our patient has intense fever, due to the constant production of pus, and is in imminent danger of falling into the hectic state, with all its consequences. We should not, however, be too positive, for similar cases are on record, where complete recovery ensued.

What treatment is to be pursued ? I will not discuss the opportunity for direct intervention, for thoracentesis is evidently not indicated. We will then, on the one hand, attempt to moderate the violence of the inflammation, and on the other, sustain the strength of the patient.

To fulfill the first indication we apply successive flying blisters to the affected side.

To respond to the exigencies of the second, we administer tonics, soft extract of cinchona, brandy and the more generous wines. Need we have recourse to any form of antiseptic medication? The use of antiseptic preparations and simple or aromatic fumigations is undoubtedly rational, but has as yet hardly received the sanction of practical clinicians.

NOTE.—To complete this lecture and observation it may be added that the patient submitted to the treatment above indicated ; after several attacks of purulent expectoration, the quantity discharged being each time lessened, finally recovered completely, and left the hospital on April 14th, in excellent health.

Communications.

INTRODUCTION TO STUDIES IN CLINICAL GYNECOLOGY.

BY PROF. A. J. C. SKENE,
Of Brooklyn, N. Y.

The fact should be clearly kept in mind that a knowledge of the science of medicine does not give skill in the art of practice, however much it may help one to learn it.

Men profoundly versed in the science of medicine may be poor practitioners, and men whose knowledge of the science is very limited may attain some reputation in practice. The best qualified physician is the one who knows most of both the science and the art. The subject for consideration to-day is the methods of investigation to be adopted in practicing the art of gynecology. Before beginning the actual work of examining patients it is necessary to know how to do so.

There are several methods of investigating the sick and injured, given in text-books and taught by professors, but most of these are better adapted to general practice than to special departments of medicine.

The methods which I desire to teach you are circumscribed, and perhaps less complicated because they are limited to the diseases peculiar to women.

In examining patients you must first settle definitely in your minds the object to be attained and how to attain it. Some rational system of investigation should be mastered in all its details before undertaking actual practice. To engage in clinical study without such preparation is like trying to read a language without knowing its alphabet.

First obtain all the facts of the case in hand; secondly, arrange the facts in their natural relation to each other; and finally, make deductions from the data obtained.

These will be easily remembered in the following order and association: observation, classification of things observed, and conditions indicated by the sum of the information obtained.

I desire to urge you to give special attention to the art of observation, because it is often neglected by teachers and students. The systematic way in which facts are presented in books and oral lessons enables the student to acquire the habit of classification in all branches of learning. The mental training obtained in the study of mathematics and logic prepares men to make reasonable deductions from the facts in science; but I know of no school in which thorough training is given in the art of observation. It is because of this defect in preliminary education and in learning clinical medicine, that practitioners are led into error sometimes, in making diagnosis. They fail to observe all the facts, and hence their deductions are liable to be incorrect.

One who misses a page here and there, in reading a book, is in constant danger of misunderstanding the author. The examination of a patient should begin by a general inspection; and in order to make that inquiry complete and profitable, certain questions should be raised in the mind of the examiner; such, for example, as what is the general appearance of the patient under observation? What size? Regular or defective in general outline? Lean or corpulent? What temperament? Is the face pale or flushed? Languid or vigorous? Sad or cheerful? Calm or excited? Intelligent or stupid? What diathesis is indicated, if any? In short, does the general physiognomy indicate health or disease.

All these interrogations are made by looking inquiringly at the patient. There are so many questions to be answered in this connection, that you may find some difficulty in promptly remembering them; but by patient practice you can train your mind and eyes so that you can take advantage of a rule of observation employed by critical investigators, which is this: having a type of a normal organization in mind, you can scan a given case, and detect any deviation from the standard of healthy formation and appearance. The artist, in looking at a picture or statue, does not necessarily question every line of the drawing or form by itself, but his trained eye catches any defects that there may be in the work before him.

Just here a brief reference may be made to arrangement of the information obtained by an examination.

The classification of facts is simply putting together those which are similar in character. The arrangement of material things in groups is familiar to all of you. A well arranged library, in which all books pertaining to a given subject are placed side by side, is a fair illustration of this kind of classification. Facts and ideas can be arranged in the mind upon precisely the same principles. The advantage of classification is that it aids comprehension and memory. By recalling one of a group of facts which have been associated in the mind, the rest will follow in easy and natural order. There are two methods of classifying the points in the clinical history of a patient. One

is to obtain all the information possible, and then arrange it in order. The other is to classify the facts obtained at each step of the examination. The former method requires a mental grasp and tenacity which few possess, and therefore I would advise you to adopt the latter.

The information obtained by inspection may be classed under four heads: *First.* The original character of the organization, whether perfect or imperfect in general outline. *Second.* If imperfect, whether by imperfect development, giving lesions of form, lesions of structure from inherited or acquired disease, and inherited tendencies to disease, known as diathesis. *Third.* Evidences of disease, expressed in the face, either acute or chronic, and of what class. *Fourth.* The temperament, which simply means the preponderance of a certain portion or portions of the organization. It is quite important to be able to recognize the temperament of each patient, as it has a bearing upon the tendencies to disease. The term temperament is an unfortunate one, because it does not give any idea of the meaning implied; but long use has given it claims which cannot be easily set aside. I have observed that students often fail to clearly comprehend the use of the term in clinical medicine. Hence, a brief explanation may be profitable.

You are aware that in describing the human organization, it is divided into four sections, or systems, the nutritive, circulatory, nervous, and muscular, which includes the osseous structures. Now, when either of these systems predominates in extent of development in a given person, we say that he or she possesses that temperament. There are, therefore, four temperaments, viz., the *muscular* (called bilious), the *nutritive* (called lymphatic or phlegmatic), the *sanguine*, and *nervous*.

In a uniform and well developed organization neither system predominates. They all exist in normal proportions. Examples of this well balanced type of organization are said to have been presented by such men as Washington and Franklin. We have at present no suitable term to designate such organization, in which all parts are equal in development. Such a condition represents a typical union of all the temperaments; the highest order of normal development. Two of these systems may predominate, which gives what may be called a compound temperament. For example: the nervous and circulatory systems being more developed than the rest of the body would give the sanguine-nervous temperament. And so by the combination of two of any of the systems the other compound temperaments are formed.

A few examples of what may be accomplished by inspection will tend to fix in the memory what has been said upon this subject. Suppose a patient appears to be about the average size, well formed, full in flesh, small bones, fair hair, blue eyes, pale face and lips, and facial expression of weariness and discomfort. These conditions would indicate the phlegmatic temperament, and, perhaps, the strumous diathesis, anæmia, mental discomfort and want of general strength. Take another patient, tall, and spare in flesh, large bones and muscles, large brain, dark hair, and sallow, dry skin; the face expresses suffering and an excited, restless condition; these characteristics indicate the nervous-bilious temperament, faulty nutrition, probably from some organic disease which gave rise to physical suffering.

To illustrate still further the value of this process of general inspection of patients, let me state the partial history of a case seen in private practice. A lady called to consult me regarding her son, a little fellow seven years of age. After a very brief survey of the patient I informed his mother that he had recently had scarlatina, and that within a few days his feet had been swollen; that his urine was scanty and of a peculiar dark color, as if mixed with soot. I also stated that when a child he had suffered from sore eyes, and when an infant he had snuffles, and that his father had been subject to rheumatic pains in years gone by. All this was told to the mother before asking her any questions and before examining the patient further than to look at him. She acknowledged that I was right in every particular, and expressed surprise that I should know so much of one whom I had never seen or heard of. In the estimation of my client I had established a reputation upon which an enterprising character could have made a fortune. When I told her how I made these discoveries, she at once understood that it was simply a matter of clinical observation. A glance at the boy showed that exfoliation of the cuticle, which occurs after scarlatina, was still going on; the face was pale and puffy, indicating commencing dropsy from acute nephritis, a sequel of the eruptive fever. I also noticed that he had a delicate scar upon the cornea of each eye, the result of a former keratitis. The form of his nose and the character of his teeth indicated an inherited syphilis, and from the appearance of his mother and other facts in sociology I presumed that the father was the one who transmitted the specific disease.

EVIDENCE OBTAINED FROM PATIENT'S TESTIMONY.

The *age* of the patient should be ascertained, because that suggests the possible existence of the diseases which are likely to occur at certain periods of life. Care should be taken to compare the real and apparent age, in order to tell if the patient is prematurely old or well preserved. This interrogation will also serve to keep in mind the fact that, in early life, acute diseases prevail, while degenerations are usually limited to advanced life.

It is important to know the social relations of a patient—that is, whether she is married or single. If married, she is liable to the diseases and accidents attendant upon child bearing. A married woman who has never been pregnant, suggests that she is possibly sterile, either from choice or because of some defect in her organization. Single women ought to be limited in the range of diseases of the sexual organs, and we may take it for granted that they are until we obtain evidence to the contrary.

Having made a general inspection of a given case, and learned the age and social relations, an examination of the various portions of the body should be made, in systematic order. To do this conveniently, one group of organs should be examined at a time. This group of organs constitute the various systems, classified as follows:—

THE NERVOUS, NUTRITIVE, MUSCULAR, AND SEXUAL SYSTEMS.

The first three are subdivided as follows: The nervous has two grand divisions, the cerebro-spinal and organic. The nutritive has four subdivisions, the digestive, circulatory, lymphatic and excretory, and the third has the osseous and muscular.

The present purpose is to outline the methods of investigating the sexual system, but in order to do that successfully, it is necessary to be able to examine the whole body. No one can be a trustworthy specialist without having a thorough knowledge of the whole organization. All the parts of the body are so bound together by mutual relations that one cannot accurately diagnosticate the diseases of one portion without knowing the condition of all the others. On account of that fact I must refer to the principles upon which the examination is made of parts other than the sexual system.

Briefly, it may be stated that the two principal subjects of inquiry are the condition of the function and structure of the organs under examination. Perverted function of the cerebro spinal division of the nervous system is manifested through derangements of sensation and motion, and abnormal states of the organic nerves is indicated where nutrition is deranged, while the organs of nutrition are free from organic disease. The condition of the circulatory system is indicated by the color of the skin and mucous membrane; the character of the pulse and the heart sounds.

General nutrition may be estimated by the appetite for food, the excretions and the state of the flesh generally. These are meagre hints, but if you keep them in mind while examining cases in the department of gynecology, you will guard against overlooking affections of the general system which might modify or cause diseases of the sexual system.

In applying the principles (already hinted at) in the investigation of special diseases of the sexual organs, we find that morbid action is manifested by symptoms and physical signs. The symptoms may be classed under three heads. First, deranged nerve action; Second, deranged functions of the organs affected; and, Third, modified muscular motions.

The First Class (Nerve symptoms). Pelvic pains not specially localized; sacral pain; pain of special pelvic organs; pains beginning in the pelvis and radiating to other parts of the body.

Second Class.—Derangements of function; state of the functions; deranged menstruation; sterility; abnormal discharges; deranged function of the bladder and rectum.

Third Class.—Aggravation of any or all the above named symptoms, by standing, walking, or any other muscular exercise.

Keeping this classification in mind will suggest questions, the answers to which will determine the presence or absence of these symptoms. You should know the symptoms which belong to a given case, and then ascertain if they are present by asking the patient questions. You will more surely obtain correct testimony in that way than to depend upon voluntary statements made by the person examined.

The following will aid you in understanding the way to detect the symptoms referred to in the three classes given above. First ask if the patient has pain and where it is located. Ascertain also if this is pain connected with any of the functions of the pelvic organs. Then obtain the history of the functions of the sexual organs, in the past and present. These facts can be obtained from the patient herself, aided, perhaps, by some one who knows her well. Some practice is necessary to give skill in taking testimony, the value of which depends largely upon the physician's

ability to make the patient answer his questions correctly. Such questions as the following regarding the menstrual function should be asked. At what age was the menstrual function first established? At what periods of time has it recurred? How long does it continue each time? What is the quantity and character of the flow?

Is it attended with pain, and if so, where is the pain located, and the time it occurs in relation to the menstrual flow? Has menstruation always been attended with pain, or only for a limited period in the history of that function? And, finally, is menstruation attended with derangements of any of the other functions of the body?

From the answers to these questions two points can be decided. First. Whether menstruation has been performed normally during the whole, or part of the patient's menstrual period of life, and Secondly. If any derangement of that function exists, whether it be in character, recurrence, duration or quantity.

Next in order comes the history of reproduction. Has the patient had children, and if so, how many and when? Has she miscarried? If she has, at what period of gestation, and at what time in relation to birth of living children if she has had any? Was there anything abnormal in her pregnancies, confinement, or recovery from labor; if so, what? The answers to these questions will show whether the present conditions date back to some of the diseases or accidents of pregnancy or parturition. If the history so far obtained indicates any disease or functional derangement of the sexual organs, and there is any accompanying affection of the general system, the question arises, regarding the relations which they sustain to each other. That question can frequently be settled by ascertaining which of the two affections, the local or general, appeared first. The one which precedes is frequently the cause of that which follows.

Thus far we have been dealing with symptoms which, as a rule, only reveal derangements of function. They are only expressions of disease, and do not in all cases indicate the conditions of the organization which cause the derangement of function. This brings us to the final division of our subject, viz: Physical signs of disease. These are the physical evidences of changes of structure. There are exceptions to this rule, but they are few in number, and therefore, may be omitted in our general consideration of this subject.

The changes of structure and organization of the sexual organs which are expressed by physical signs are as follows:—

Changes of position, form, size, consistence, composition, color or appearance.

The means of observing physical signs, are by the touch, single or bimanual; speculum, sound and curette, percussion, palpation, exploring needle, uterine dilators.

The art of employing these means, and the significance of the signs obtained thereby, can only be taught by actual cases presented in the clinic for diagnosis.

Hospital Reports.

BELLEVUE HOSPITAL, NEW YORK.

CLINIC OF AUSTIN FLINT, M.D.,

Professor of Principles and Practice of Medicine in Bellevue Hospital Medical College, New York.

Carcinoma of the Peritoneum and Pleura(?).

Gentlemen:—The record of this case reads as follows: The patient is a woman, fifty-four years of age, who was admitted to the hospital on the third of this month. She has been a hard-working woman, obliged to support herself by scrubbing, etc.; she has never been in the habit of taking stimulants; the general health good; has been troubled with hemorrhoids and constipation; about two months ago she noticed that her abdomen was beginning to become enlarged, and this enlargement rapidly increased until she was unable to be up and work. She consulted a physician, who drew off about two gallons of fluid from her abdominal cavity, after which he was able to feel a tumor. The abdomen refilled with fluid and became largely distended; her appetite failed, and she has been losing strength for some time. There has been no vomiting; no swelling of the feet or of the face; no cough; there has been shortness of breath; no pain; she is pale, but well nourished; she came into the hospital on account of the abdominal enlargement.

On inspection we see a peculiar bulging of the upper part of the sternum, probably congenital. The percussion note in the left infra-clavicular region is vesiculo-tympanitic; the respiratory and voice sounds are exaggerated. Below, we have all the signs of fluid in the left pleural cavity, rising as high as the level of the fifth dorsal vertebra.

The abdomen is noticed to be considerably enlarged, and there seems to be a slight bulging at the level of the umbilicus. Palpation shows that the abdominal wall is not very thick, not tense, but soft and yielding, and that fluid is present in considerable quantity. There is bulging just to the left of the umbilicus, due to the presence of a hard mass, which is somewhat movable under the hand. There is a second tumor, not quite as large as the first, in the right iliac region, which is also movable, and apparently is not attached to any of the pelvic viscera. Both tumors are firm and resistant, and do not feel like fecal masses. It is always a question, when we find tumors here, whether they may not be due to accumulation of hard, fecal masses in some portion of the

colon. This subject we will soon consider in the didactic course.

Above the level of the fluid there is tympanites. Dullness and tympanites change with the change in position of the patient. On auscultation, a rubbing friction sound is heard as the tumor is moved.

The heart is somewhat displaced to the right. The urine presents no evidence of disease of the kidneys.

The patient has been put upon tonic treatment and good diet.

It is noted that on the fourth, when fluid was withdrawn from the pleural cavity, it contained red globules and budding cells. These signs are to be regarded as diagnostic of carcinomatous disease. As a rule, when we withdraw liquid from the chest, and it contains a little blood which cannot be accounted for by the puncture made, it may be taken as proof, though not absolute, that there is either phthisis or carcinomatous disease.

On the eleventh it is recorded that the patient is now quite comfortable, but at times, however, she is troubled with shortness of breath. The bowels are constipated, but always respond to laxatives. The appetite has not been good; occasionally vomited during the last three days; the abdomen to-day is larger than at the beginning, the enlargement being apparently due to tympanites. The percussion note is tympanitic over the whole of the abdomen, and no evidence of fluid is obtained. On introducing the hypodermic needle failed to get any fluid.

Another specimen of fluid was withdrawn from the left pleural cavity, and submitted to Dr. Welch for microscopical examination. He reports that "the fluid contains a large number of red blood corpuscles, a few pus cells, and a considerable number of oval or round cells, two or four times the size of red blood corpuscles. These large cells occur singly and in groups. They often present the appearance of so-called budding cells, one cell, as it were, springing out of another. The size of these cells, and their occurrence in groups, and as budding cells, renders probable the diagnosis of carcinomatous disease of the affected serous membrane."

Such is Dr. Welch's report, and it is with reference to the diagnosis of carcinoma of the pleura that I wish specially to present the case to you to-day. You will remember that at a previous clinic I gave the details of a case in private practice, in which there was hydro-peritoneum, and at that time no evidence, on palpation, of carcinomatous disease could be ascertained, but it was suspected, and for the same reason that we should suspect it in this case if we had not found a tumor, namely, absence of the ordinary causes of hydro-peritoneum. There were no evidences of disease of the liver. The habits of the patient, so far as we could judge (and I think we could judge correctly), would exclude the probability of cirrhosis. There was no evidence that the dropsy of the abdomen was preceded by peritonitis, at least, of any degree of acuteness; nor was there anything preceding the ascites to denote renal inflammation.

Here, then, we have an instance, assuming our diagnosis to be correct, of pleurisy dependent upon carcinomatous disease occurring in the chest. There is considerable fluid in the chest, but it has not yet embarrassed the respiration seriously, even though associated, as it is, with tympanites and a certain amount of liquid in the peritoneal cavity. But if at any time further accumulation of liquid in either of the two cavities should render the respiration very difficult, it will be proper to remove some of the liquid by aspiration. At present, however, the two indications evidently are to sustain and invigorate the patient by tonic remedies and by good, nutritious diet.

Bronchitis.

I may state, gentlemen, that the case, which I presented to you at a former clinic, of bronchitis affecting the smaller sized tubes (though not extending sufficiently, perhaps, to constitute capillary bronchitis), associated with collapse of the lobules or lobular pneumonia, has been improving progressively, and the patient is now in a comfortable condition. The physical signs which denoted circumscribed solidification of the lung have, as I learn, disappeared. You may also recollect the patient presented some time ago, who had anæmia and functional disturbance of the heart, and was confined to the bed. She is now able to assist the nurse about the wards.

Bright's Disease.

I will now present you two patients with chronic Bright's disease of the kidneys. I have not during this session been able to present you cases well illustrating all the varieties of this disease. Besides the general division into acute and chronic renal disease, we have different kinds of the chronic form, and among these, I may mention, first, the large white kidney, combined often with the waxy, which presents a certain group of symptoms. I do not think I have yet been able to show you a good typical case of this variety; that is, a patient with a large amount of anasarca, marked pallor of countenance, the urine loaded with albumen, and so on. The acute form of Bright's disease, when it becomes chronic, presents this variety; it also follows scarlet fever, and exposure with intoxication.

Then there is the waxy form of kidney, the diagnosis of which we can form from the antecedent history—prolonged suppuration from some part of the body, disease of the bones, syphilis, sometimes phthisis; and sometimes there is evidence of waxy disease affecting other organs, as the liver, the spleen, and sometimes the intestines. The anasarca in this variety is considerably less than in the former, sometimes it is entirely wanting: the progress of the affection also is frequently very slow, the urine is abundant, of low specific gravity, and contains a small amount of albumen and hyaline casts. These are points involved in the diagnosis.

The other variety is the fibroid, the cirrhotic or contracted kidney, and it has so happened that our cases, so far, have been in illustration of this form. This form is of special interest in this respect, that is often overlooked, the ordinary symptoms and signs of Bright's disease, perhaps, being wanting for a good while, the first evidence being, perhaps, the sudden development of some important sequelæ, or complication. There may be entire

absence of general dropsy; examination of the urine may show only a trace of albumen, or none whatever; and if we are content with a cursory examination of the urine, we may reach the erroneous conclusion that there is nothing in it denoting this disease. This happens over and over again, the examination of the urine not being sufficiently minute. The quantity should be well ascertained. The specific gravity should never be overlooked, and the examination by the microscope in these cases is often of considerable importance.

With regard to the usual complications of this form of Bright's disease, they belong among the uræmic manifestations, and are supposed to be due to retention in the blood of urea. It is a question, however, whether other principles are not also retained, or whether it is the urea alone which causes the toxical effects. However that may be, it is in consequence of the retention in the blood of matters which should be eliminated, that we have the manifestations of uræmia. Of these symptoms I make this division, namely, into the minor and graver, and I think it is a practical and useful one. The minor manifestations are very important to us in practice, as leading us to suspect, in given cases, the existence of Bright's disease. They are, pain in the head. or cephalalgia, nausea, vomiting, diarrhœa not otherwise explained, impaired vision. Over and over again patients have gone to the oculist for disease of the eye, and on examination, the oculist, knowing about the dependence of disturbed vision upon disease of the kidney, in certain cases, has made the diagnosis of Bright's disease. Cramps in the limbs may be mentioned in this connection.

Now and then the graver manifestations of uræmia are the first to attract attention—coma, convulsions, sometimes occurring suddenly, sometimes not. The minor usually precede the graver manifestations, but not always. Bear in mind that fact. Now and then a patient may appear in his usual health, be about his affairs, when suddenly he drops down in the street, unconscious, in a state of coma, sometimes with convulsions.

Now, when we examine a patient, and find these minor uræmic manifestations present, it is important for us not to overlook their possible or probable significance. I want to make one practical remark here with regard to the examination of the urine. In all cases in which there is any ground whatever for suspecting renal trouble, examine the urine, and examine it with care. I have come more and more to consider it important, in all doubtful cases, to have a sufficiently careful examination of the urine made, either to determine the probable existence of renal disease or to exclude it.

Besides coma and convulsions, there are pericarditis, pleurisy, œdema of the glottis, œdema of the lungs, dyspnœa which is apparently toxical, we being unable to refer it to any appreciable morbid condition of the lungs, and, therefore led to infer that it proceeds from the action of toxical principles in the blood upon that portion of the nervous centre which presides over the respiratory tract. We meet with cases of this sort which are referred to uræmia. Such are the more important of the graver manifestations.

The two patients which I present to-day, gentlemen, happen to be cases illustrating the sudden occurrence of grave uræmic manifestations. That is, assuming the condition of the second patient to be that of Bright's disease and uræmic poisoning.

This patient, a woman, forty six years of age, was presented to you on a former occasion, when I read her history. You will remember that she came from out of town to the city, and here became suddenly unconscious, and was brought to the hospital in that condition. There has been no œdema of the limbs, but examination of the urine showed the existence of renal disease. There has been considerable mental disturbance since her entrance into the hospital. There has been delirium, which is not a very frequent complication of renal disease, but sometimes it is, and is sometimes a very important symptom or complication. I have known violent mania to occur in connection with this variety of Bright's disease. From the time she was presented before until about a month since this case was progressing very well; nothing of any particular importance occurred; but since that time the points are of interest, and I will read the record. She has been passing from fifty to seventy ounces of urine daily, but on the 4th the amount dropped to 34 ounces, and during the night she vomited and complained of nausea. Note the connection between these gastric symptoms and the very considerable and sudden diminution in the quantity of urine eliminated. The next day she still had a good deal of nausea and some vomiting. Bicarbonate of soda in water was given, but it seemed to increase the nausea instead of relieving it. I suppose the alkali was given to diminish the effect of the eliminative matters upon the mucous membrane of the stomach. You will remember that in a former case there occurred almost complete suppression of the urine, and the gastric symptoms became greatly aggravated.

On the 5th the amount of urine passed was 28 ounces; nausea and vomiting continued, and there was dizziness, spots before the eyes, and headache. You will notice the appearance of minor manifestations of uræmia occurring after her admission to the hospital: before that there being none; the first symptom of renal disease showing itself in unconsciousness

She has been taking the infusion of digitalis three times a day, and later every three hours. There is still no œdema in any part of the body. A tenth of a grain of elaterium was given, and again repeated, but it had no effect. This, I am sorry to say, is frequently the case with this drug, that it is variable in its strength, and we are liable to get negative results. Infusion of digitalis, liquor ammonia, and spirits of nitre were then given, and during the day 27 ounces of urine were passed. She was then given a mixture which contained jaborandi, and this had the effect of producing diaphoresis. You are aware that one of the means of eliminating urea vicariously is by the skin, and measures to accomplish this are important. We can use various external methods to produce sweating, but jaborandi is a remedy which sometimes has a remarkable effect in that

direction. As far as my experience goes, however, its good effects in cases like this have not been fully met. Notwithstanding she perspired freely, the symptoms were not much relieved. On the 9th the compound jalap powder was given, but it did not move the bowels. I have often found that this, in some cases very efficient hydragogue cathartic, the pulvis purgans, fails to act, so that I have hesitated to employ it in urgent cases, cases in which it is very important to have drugs that can be relied upon. At 9 P. M. on the 9th the mixture of digitalis was stopped, and one-tenth of a grain of elaterium was administered. At 12 P. M. the specific gravity of the urine was 1.016, and she passed only 10 ounces; but the amount was not very accurately measured. On the 10th she had several very large movements of the bowels, the elaterium seeming to have taken effect. A solution of morphine was administered hypodermically, to relieve pain, and she received a stimulant. During the past twenty-four hours she passed 46 ounces of urine; free from nausea and dizziness. During the next twenty-four hours the amount of urine passed was 28 ounces, of a specific gravity of 1.010; contained no albumen.

The points of instruction in this case, gentlemen, are these: Here is a patient who was admitted into the hospital, having been suddenly attacked, without any known previous symptoms pointing to any important disease, with coma and convulsions. Examination of the urine showed unmistakably disease of the kidneys, and of that variety of chronic Bright's disease known under the several names of small, contracted, cirrhotic, fibroid, gouty kidney. She improved in the hospital, until suddenly, without any apparent reason, the urine dropped down from an increase in quantity to a smaller quantity, and coincident with this we had minor manifestations of uræmia, especially nausea and vomiting. Then the object of the treatment was to forestall the occurrence of the common and graver manifestations of Bright's disease.

Now, that is the problem which is presented to us frequently in practice, and in order that we may do that, it is important for us to ascertain, by proper examination, the fact of the existence of this form of Bright's disease. You see difficulties exemplified in this case which we meet with in practice. The stomach was not very tolerant of remedies. Elaterium was employed, but at first seemed to be ineffectual. Pulvis purgans, and other hydragogues, either from defect in the drug itself, or from some condition of the patient, proved unsuccessful in this case. Finally elaterium was repeated, and it then proved successful, copious watery discharges being produced, and then the minor symptoms which we had a right to conclude might foreshadow graver ones were temporarily removed; so far, then, this case affords us instruction, and its subsequent course may develop other points which may be interesting and useful for us to consider.

The other patient whom I shall present to you was also taken suddenly with coma and brought to the hospital in that condition. The urine gave some evidence, not much, of renal disease. It was found to be very small in quantity, and it was then concluded that the coma, and also convulsions which she had, were due probably to uræmia. She improved, but after a time the urine again became greatly diminished in quantity, approaching even to suppression, and there came on intense gastric irritation, and you will remember that I presented that patient to you a second time with reference to that complication of renal trouble. The stomach was intolerant of everything, and it was necessary to sustain the patient by rectal alimentation for some time.

Now, the problem in this case was, had we sufficient evidence on which to make a diagnosis of disease of the kidneys. The evidence was rather small; I mean evidence afforded by examination of the urine. There was sometimes found, but by no means constantly, traces of albumen, and two or three casts were also found. These facts, together with that of almost total suppression of urine, led me to suppose that this was a case of uræmic convulsions, probably due to renal disease.

It is noted that on the 3d instant the patient feels more comfortable; the stomach retained beef juice and milk; 17 ounces of urine, specific gravity 1.026, amber colored, acid, contains no albumen. Although the amount of urine passed was small, you will notice that the specific gravity was high, and this is an important fact. The quantity of the urine and its specific gravity should always be considered together.

On the 4th she felt well, passed 26 ounces of urine, amber colored, turbid, specific gravity 1.020, acid, no albumen. Notice that with this increase in the quantity of urine the stomach is able to retain liquids. On the 8th it is noted that she has been steadily improving, the quantity of urine increasing, being on the 6th 45, on the 7th 25, the 8th 32, on the 9th 40, and on the 10th 60 ounces. It contains no albumen; specific gravity about normal. She sits up all day, and feels well.

Such, gentlemen, are the facts in this case. Had the patient, before developing more plainly uræmic symptoms, come to you in private practice, it is altogether probable that on examining the urine and finding it to be, as it has been in this case, almost or quite free from albumen, you would say at once that there was no disease of the kidneys; yet you see the progress of this case has been such as to point, without much doubt, to the existence of renal disease. The occurrence of coma, along with the great diminution in the quantity of the urine, and the uræmic manifestations in connection with the digestive organs, make it difficult for us to conclude that the kidneys are free from lesion.

Medical Societies.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated meeting, May 4th, 1883. The President, Dr. E. L. Duer, in the chair.

Dr. Boardman Reed, of Atlantic City, New Jersey, remarked that the questions of most interest with regard to

Icterus Neonatorum

are its etiology and pathology, and its relations to

umbilical hemorrhage and purpura. As to the first of these points, we can arrive at satisfactory conclusions only after an extended series of autopsies, such as it is rarely or never the privilege of the physician in private practice to see. The wards of lying-in hospitals ought to afford the needed data to determine finally whether jaundice in the new-born originates in the liver or in the blood. A sufficient number of thorough post-mortem examinations do not seem to have yet been made to set this question at rest, hence, we find a variety of theories maintained.

The theory advanced in many of the older books is that the retained meconium forms an obstruction to the escape of the bile. This does not seem to have been confirmed by post-mortem examinations, and is improbable, from the fact that icterus usually does not develop in infants until several days after birth, and after there have been numerous fecal evacuations.

Some of the German authorities consider that icterus neonatorum is probably due to lowering of the blood pressure in the hepatic capillaries, in consequence of the cessation of the blood stream passing directly from the umbilical veins into the portal vein. This at first appears plausible, since experiments upon animals, conducted by Heidenhain and Lichtheim prove that lowering the blood pressure in the liver, as by starvation, or by establishing a biliary fistule, may cause all the phenomena of jaundice. But as this change in the circulation must take place in every infant immediately after birth, we should expect jaundice to be universal in the new-born, and to come on always within a day or two after birth; whereas, it affects a very small proportion of the whole number of children born, and is generally developed between the third and tenth days.

It seems more probable to me that jaundice in the new-born (excluding the transient yellowish discoloration due to the natural fading of the rosy color first seen in healthy infants) may arise from at least two wholly different causes, and is, therefore, divisible into two classes, one obstructive or hepatogenous, and the other of hemic origin or hematogenous. The first we have reason to believe originates most frequently, as in adults, from a catarrh of the duodenum or bile ducts, which we might expect, *á priori*, to result during the first week of life, from the ablutions to which many infants are subjected under circumstances that render the taking of cold almost unavoidable before a tolerance has become established.

That exposure to cold is one frequent factor in producing the disease, is well known. It is recorded by West that in the Dublin Lying-in Hospital, where the hygienic conditions are excellent, infantile jaundice is very rare; while in the Foundling Hospital, at Paris, few infants escape it; nearly all the abandoned little waifs being exposed to cold before admission.

It is doubtless true that jaundice dependent upon persistent obstruction, occlusion, or congenital absence of the bile ducts, instances of which have been observed in infants, may go on to the production of profound blood changes and be complicated with hemorrhage as a consequence, from the umbilicus or mucous surface; but I am disposed to maintain that many of the grave cases associated with such hemorrhages are of hemic origin. The reasons for this view are (1) The constantly observed fact that the most intense forms of obstructive infantile jaundice are often accompanied by light stools and high-colored urine, and yet unaccompanied by any tendency to hemorrhage. Several of my cases exemplify this fact, and notably, the one hereinafter reported, of a child born with measles and shortly afterward developing jaundice. Every practitioner must see many cases of severe, yet uncomplicated jaundice. On the other hand, persistent and fatal hemorrhage now and then occurs in cases where the jaundice is only slight. Many such are on record; nor can it be assumed that the connection is only accidental, as the statistics, to be cited further on, abundantly establish a causal relation between jaundice and hemorrhage. (2) The fact that these hemorrhagic cases associated with slight jaundice do not usually present any marked evidence of obstruction to the flow of bile; such as constipation, white stools, etc. (3) The fact that they occur frequently under conditions, such as immaturity and feebleness at time of birth, which have no obvious connection with hepatic obstruction, but are most likely to be dependent upon an inheritance of poor blood from the maternal system, or of digestive and assimilative powers so weak that the elaboration of healthy blood by the infant organism is impossible.

These reasons, I submit, render still tenable the theory that infantile jaundice may have other than a hepatic origin.

The relations of icterus neonatorum with the hemorrhagic condition manifested most often by bleeding from the umbilicus is a subject of much interest and practical importance, concerning which the profession is in need of more exact information. That there is often a dependence one upon the other is certain. Among two hundred cases of spontaneous umbilical hemorrhage which have been reported, including two of my own, jaundice was observed in seventy. It probably existed in a slight degree in a much larger proportion, not being considered of sufficient importance to report; but even the above recorded ratio of more than one in three is sufficient to prove a causal relation, since in any unselected two hundred births we should not expect to have more than ten or fifteen cases of jaundice, instead of the enormous number of seventy.

Spontaneous umbilical hemorrhage is so rare that many physicians of extensive experience have never seen it. West, in the first edition, gives a better description of it than most recent writers on diseases of children. He emphasized particularly the fact that it may depend upon a grave form of jaundice, but states that he had never met with a case of it.

This complication being so rare, I shall not apologize for briefly summarizing here a report of an interesting case of it, seen two and a half years ago, in Atlantic City.

Case 1.—A female child, born two weeks, at least, before term; weight about six pounds. The mother had suffered at times, for years, from anæmia, palpitation of the heart and various hysterical symptoms. During the pregnancy she

had nausea almost constantly, due to disease of the cervix. Vomiting was so severe and frequent toward the close of the period that her health was greatly impaired by it. I was on the point of applying nitrate of silver to the cervix when, after a number of uterine hemorrhages, extending over a week, labor came on and the child was speedily born. The father was even more delicate than the mother, having chronic dyspepsia, periodical sick headache and nervous exhaustion.

After the delivery the cord was secured with a double ligature, and there was nothing abnormal until the fourth day, when the compress over the umbilicus was found saturated with blood, which oozed from all parts of the softening funis. Numerous powerful styptics were applied, with only temporary good results, the bleeding, though checked for a time, always recurring after the lapse of a few hours. Dr. W. H. Bennett was called in consultation, and the day after the hemorrhage began hare-lip-pins were inserted through the tissues beneath the umbilicus, and the mass ligated. This greatly diminished the bleeding, and the following day the ligatures were tightened, with the effect of finally stopping it. Ergot and tincture of the chloride of iron were administered in very small doses, with a view to modifying the hemorrhagic diathesis which evidently existed. Before the hemorrhage was controlled spots of purpura appeared on the forehead and other parts, jaundice developed shortly after the bleeding began and became marked enough to be noteworthy, but was at no time intense; the stools continued unchanged in appearance, with a tendency to diarrhœa rather than to constipation. The mother having no milk, the child was fed artificially from birth. Shortly after the hemorrhage ceased a volunteer wet-nurse suckled the child for several days, with manifest advantage. When artificial feeding was resumed diarrhœa set in and became troublesome; appropriate treatment and a change from cow's to condensed milk checked the bowels, but the child failed steadily, nutrition evidently being irreparably damaged, and some icterus persisted until the seventeenth day, when it died. No autopsy was permitted.

As an interesting supplement to this report, I may add that a few months ago another child was born to the same parents, and has the following history: It was a male, and somewhat larger at birth than its predecessor. On the second day there was some oozing from the funis, in spite of two ligatures most carefully applied, but this was so readily controlled that it would scarcely have received a second thought, except for the serious hemorrhage in the previous child. As showing the feeble and neurotic constitution bequeathed to these children, it may be mentioned that this infant had a convulsion on the second day after birth, and has had similar seizures at frequent intervals since. It has shown no jaundice at any time.

As a striking example of hepatogenous jaundice in the new-born, the following report is introduced:—

Case 2.—The mother, while pregnant, contracted measles in a severe form; the rash, after being out well, retroceded; pneumonia then developed and she then aborted, some two or three weeks before term. The child, which was of fair size, weighing upward of seven pounds, was covered with a faint rash at time of birth, and within a day or two presented the usual symptoms of the exanthem, including the catarrh, though the fever was slight. By the fourth day its skin began to turn yellow, and there was rapidly developed a very intense form of jaundice, the color, at one time, becoming almost olive green. There was constipation, with one hard, white, putty like stool daily, urine high-colored, staining the napkins. The liver seemed abnormally small; the region of dullness on percussion measuring about one and a half inches in the mammary, and one inch in the axillary lines. The child was fed first with diluted cow's milk and later with condensed milk. I saw the case on the ninth day from birth. Jaundice was then very marked, the hue being of a greenish yellow; but there had been no hemorrhage, either from the umbilicus or any other part. The child manifesting considerable appetite, apparently fair digestion, I ventured the opinion that it might possibly survive, though an unfavorable prognosis had previously been given. It recovered gradually from the jaundice, which lasted in all some twelve days, but has since suffered severely from indigestion and is not thriving well.

Careful microscopical examinations of the blood taken from a large number of infants affected with icterus in its various forms would shed much light upon the subject; but I cannot learn that any systematic observations of the kind have been made. I regret that such an examination was not made in any of my cases; an omission to be expected of a busy physician in private practice, but one which our friends the internes in the lying-in wards of the hospitals ought not to make, amply supplied, as they usually are, with all the necessary appliances, and with authority to institute any necessary scientific investigations.

Dr. Henry Beates, Jr., Physician to the Sheltering Arms Hospital, Philadelphia, has kindly furnished me with the following notes of cases recently seen by him:—

"Having in my ward a large, plump, finely developed infant, presenting the characteristic manifestations of the so call icterus neonatorum, I submitted a drop of its blood to microscopical examination.

"The tendency to the formation of rouleaux was characteristically healthy. The corpuscles have the normal relationship of white to red. The only noticeable feature constituting what might be considered an etiological factor of this affection is a greater number of disentegrated red corpuscles and free protoplasmic nuclei. These, however, were very slightly in excess of that commonly seen under ordinary circumstances, and not sufficient, in my mind, to satisfactorily account for the intensity of the discoloration. Other symptoms of jaundice, like involvement of conjunctivæ, pigmentary discolorations by the urine, light stools, etc., were, and are positively negative. I desire to especially direct attention to the fact that this infant is well nourished and plump.

"Another case, in fact, two, presenting the same phenomena, and under the same conditions

of good nourishment, I might say plethora, have occurred recently in private practice.

"Another child in my ward, when a little less than eight days old, also presented the phenomena of icterus, but mark the contrast. The child was small, thin, and poorly nourished; its expression was one of suffering; its bottle was not eagerly sought, and vomiting frequently occurred. The bowels were constipated, and presented the peculiar clay-colored stool, and the urine stained every thing with the characteristic yellow; the conjunctivæ were also involved. After a period of two or three weeks the icterus had faded and the child is now thriving well. This is an instance of true jaundice (catarrhal) and presents features affording an opportunity of comparison with the discoloration of cutaneous hyperæmia seen almost as frequently as we see what might be termed plethoric babies."

Dr. Julius Kammerer, of Philadelphia, having spoken to me of some remarkable cases of icterus, I asked him to summarize his experience in a note, which is here appended.

"There have been cases under my observation, where the jaundice of children coincided with and was dependent on an ulceration and noncicatrized state of the navel. This cause of jaundice was so clearly demonstrated that in the autopsy of fatal cases there were found phlebitis of the umbilical vessels, extending sometimes to the portal vein, and even small abscesses in the parenchyma of the liver. In every case of icterus of the new-born, I have made it a rule to examine the navel, looking for signs of inflammation or ulceration, as the prognosis, in case of their existence, would be less favorable than in cases of catarrh or mechanical obstruction of the biliary ducts. I have seen some of these cases end fatally by spread of the inflammation to the umbilical veins or by a putrid condition of the blood subsequent to the absorption of purulent and putrid matter."

These observations of Dr. Kammerer's were partially made at the Paris Foundling Hospital, during his studies in that city, and seem to me highly important. His note was not received until after the completion of this paper, and on the eve of this meeting, else the views it embodies would have received full consideration in that portion of this paper devoted to the discussion of the etiology of infantile jaundice. It is confirmatory of my opinion that such discoloration may be hematogenous and often associated with disease of the umbilicus.

I have notes of many other cases of simple jaundice in young infants, but they would exemplify nothing more than is shown by the foregoing reports. As already intimated, the subject needs further investigation, but clinical study simply will not afford the light required. The revelations of the dead-house and the microscope, carefully and scientifically observed, can alone determine positively the points in dispute.

COLLEGE OF PHYSICIANS.

Dr. Geo. C. Harlan, Surgeon to Wills Eye Hospital and the Eye and Ear Department of the Pennsylvania Hospital, read a paper before the College of Physicians of Philadelphia, April 5th, 1882, entitled

Two Cases of Congenital Irideremia, with Lamellar Cataract in one and Dislocated Cataractous Lenses in the other.

Case 1.—N. J. M., aged 12 years, says that he knows of no defect in the eyes of any other member of his family in this or preceding generations, except that his mother is "short-sighted." He is of medium size, and, except his eyes, well developed.

His vision is $\frac{8}{cc}$ and is not improved by glasses or the stenopaic hole. There is no photophobia, and he sees better in a bright light than in a subdued one. The corneæ are clear, but perhaps very slightly below the normal size, though a constant and decided nystagmus makes it impossible to measure them accurately. The eyes are free from irritation, and their tension is normal. There is not a vestige of iris in either eye. There is well marked lamellar cataract in both eyes. In each lens there are two opaque layers with clear lens matter intervening between them, beautifully seen by oblique illumination. Only occasional and partial glimpses of the fundus can be obtained, but the choroid seems normal. There is not sufficient vision for any satisfactory test of the accommodation.

Case 2.—I. B , a well-grown boy of 13 years; has rather prominent eyes, with full-sized corneæ and normal tension, but the iris is entirely absent in both. In the right eye the cornea is quite clear, and though there are floating opacities in the vitreous, the details of the fundus can be seen fairly well. The lens, which is of normal size, is opaque and white, and is dislocated upward, so that only about its lower half is seen beneath the corneo-sclerotic junction. The ophthalmoscope shows a hypermetropia of $\frac{1}{6}$, which, assuming $+\frac{1}{8}$ to represent the loss of refractive power induced by aphakia in the emmetropic eye, indicates a structure of the ball corresponding to a myopia of $\frac{1}{12}$. The choroid and retina appear normal in structure, but the optic disk is atrophied and greatly distorted, the vertical diameter being twice that of the horizontal, and the retinal vessels crowded to its inner edge; vision is only quantitative. There is no nystagmus.

In the left eye there is a diffused haziness of the cornea, which, together with a greater opacity of the vitreous than in the other eye, makes the details of the fundus invisible. The lens, which presents the same form of cataract as that in the right eye, is still further out of position, and only a narrow edge of its periphery extends below the margin of the sclerotic. The lenses seem to be held in their unnatural position by some attachment of their upper margins, while the lower are free, and they swing backward and forward, as if on hinges, with the movements of the balls. In the left eye the lens has caused an absorption of the tissues against which it rests until the choroid has disappeared from above it and the sclerotic is very much thinned and slightly staphylomatous. When the cone of light concentrated by a convex glass is thrown upon it from below, the outlines of the lens become distinctly visible through the sclerotic.

Though irideremia (iris, and eremia, absence),

or aniridia, is an extremely interesting anatomical curiosity, it can scarcely be said, in the present state of our knowledge, to teach any useful lesson in embryology or pathology. Numerous hypotheses have been suggested to account for its occurrence, but most of them are more fanciful than philosophical, and perhaps none of them are more rational than that maintained long ago by Von Ammon, who, in view of the late appearance of the iris, after the choroid is fully formed, considered its absence as simply the result of an arrest of development of the uveal tract. It is a curious fact that this anomaly is almost invariably symmetrical. According to Manz (Handbuch, Augenheilkunde II, p. 90), but one case has been reported in which it occurred in one eye only. Another point of interest in the history of this defect is its decided tendency to hereditary transmission. A number of cases of inheritance have been reported; one (quoted from Von Ammon by Lawrence) in which one member of the first generation was affected, three of the second, and five of the third.

The fact that cataract is very generally associated with irideremia, has given some support to a suggestion that the iris is concerned in the nourishment of the lens; and to an ingenious theory of the causation of irideremia which supposes that the iris has been crowded out, as it were, by the lens remaining too long and too closely in contact with the cornea during embryonic life. This coincidence of cataract with irideremia is, however, not constant, as cases are recorded in which the lens was transparent. One is reported by Dr. Reuling (*Amer. Journ. Med. Sci.*, January, 1875), in which vision was sufficiently acute to enable the observer to determine that the power of accommodation was unimpaired.

The normal intraocular tension found in cases of iridermia has been adduced to prove that the aqueous humor is not secreted by the iris, but chiefly, if not entirely, by the ciliary processes. In the rabbit the ciliary processes are connected with the iris, and when both are removed, the eye becomes very soft and the aqueous humor is never regenerated (Deutschman, *Grafe Arch.*, v. 26, No. 3). This, so far as it goes, gives support to the advocates of sclerotomy, instead of iridectomy, in glaucoma.

Partial congenital luxations of the lens are usually upward, as in Case 2, and frequently occur without defect of the iris. In the left eye of this patient the lens is so far out of place that it would be entirely concealed if the iris were present, and this case might then be readily mistaken for one of the very rare anomalies of congenital aphakia.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Stated meeting, held Friday, February 24th, 1882, at the office of Dr. Bean, 1431 Walnut street, Dr. Harrison Allen in the chair.

Dr. McCracken exhibited a case of tumor of larynx, in a patient, aged 58 years. There were two; one attached to under surface of left vocal cord, and the other at the anterior angle below the cords.

Dr. Bean read a paper on "A Case of Paralysis of the Left Vocal Cord in Adduction Due to Anuerism of the Arch of the Aorta."

During the discussion which followed, Dr. Potsdamer gave a short history of a case of paralysis of right vocal cord, due to pressure of an anuerism of the innominate; the tumor in this case could be seen bulging into the trachea. The patient died from rupture of the walls at this point.

Dr. Sajous related the history of a case of "Vibratory Elongation of the Uvula," where touching of the uvula at any point caused it to move to the opposite side, and to curl upon itself, *i. e.*, if touched on the anterior surface the uvula moved backward, and describing a semicircle, folded itself on to the posterior surface of the soft palate. This peculiar condition had frustrated many attempts to amputate it.

EDITORIAL DEPARTMENT.

PERISCOPE.

On the Treatment of Stricture by Stretching.

Reginald Harrison, F.R.C.S., Surgeon to the Liverpool Royal Infirmary, says, in the *British Medical Journal*:—

If we put aside cases of organic stricture of the urethra which are remedied by the occasional passing of a bougie, there yet remain a certain proportion where such treatment is insufficient. To take an example: a patient having neglected the early indications of stricture, is seized with retention; with difficulty a small catheter is passed, and thus the urgency of his symptoms are met. It often happens that retention recurs, and all the difficulties attendant upon the first catheterism have to be gone over again, with, probably, considerably more spasm superadded. To meet such cases, immediately or remotely, a variety of expedients are practiced. Of these, I may mention continuous dilatation, or the tying of an instrument into the bladder; internal urethrotomy; perineal section; and rupture, as employed by Holt. All these have for their object the passing of a full-sized instrument into the bladder, without which none of them can be regarded as satisfactorily completed.

For some time, I have occasionally been employing for this object a process which I think is best described under the term "stricture-stretching." In using this phrase I do not wish to be understood as advocating the use of either a new instrument, or new treatment. I merely desire to state how I have applied well-recognized principles with equally well known means. Stricture

stretching, as I endeavor to carry it out, is very closely in imitation of the process to which gloves are submitted by the salesman after the purchase has been made. Into each stall of the glove the glove-stretcher is introduced, in order that the fingers may the more readily pass in. If the manipulation be dexterously done, neither are the seams split nor is the kid torn; if clumsily, a rent and a false passage for the finger is the result.

So much for the simile, now for the reality. The stretcher I employ is that much abused but valuable instrument, Holt's dilator; and the stretching is effected quite slowly, by the introduction of successive sizes of dilating rods, until the dimensions required are obtained. All this is to be done at one time, with or without an anæsthetic, according to circumstances. I almost invariably have the patient placed under ether, as it is important that the process should be slow enough to permit of the tissues stretching without tearing. I do not think we fully recognize the extent to which the urethra is capable of being distended. Dr. Otis, of New York, has recently demonstrated the truth of Sir Everard Home's observation: "That the urethra is everywhere much larger than had been supposed, exceeding the size of the largest bougie in use, in a very great degree." And what is true of the healthy urethra will be found to apply, though in a less degree, to the strictured one.

The adaptations in Holt's dilator, specially fitting it for this purpose, may be briefly stated. In the first place, there is attached to it a pilot bougie, which, in cases of tight or tortuous strictures, will be found invaluable. Though the pilot bougie may not be necessary for all cases where stretching is to be employed, yet, as this treatment is intended for some of the worst forms of the affection, it is as well to be prepared for every contingency. If the pilot bougie be not required, a round-top screw takes its place. Then I have increased the number of dilating rods to eight, so that the process of stretching may be gradual; and, in order that there may be no jerking as the several rods are introduced, a spiral spring controls the separation of the two portions of the instrument, instead of a screw.

The size of the dilator, before a rod is introduced, is No. 3, English gauge; the largest dilating rod brings it up to rather over No. 12; so that between these two extremes we have seven gradations in size. If the stricture is so tight as not to be capable of receiving the dilator, dilatation by means of filiform bougies must first be employed until the required size is obtained. Other instruments, divulsors and screw dilators, as they are termed, have been invented for a similar purpose; but all I have seen are open to two objections: 1. They either tear or pinch with their sides the mucous lining of the urethra; 2. They are too large for use, except for strictures of the largest calibre. One of the best divulsors I know of is that adapted by Dr. Samuel Gross, of Philadelphia. It is provided with an index at the handle, which shows precisely the extent to which divulsion has been carried.

A word or two in reference to the use of the instrument I employ for stretching. The patient being placed under ether, in the recumbent position, the dilator, with or without the pilot bougie, is passed fairly into the bladder, and then the rods are slowly and gradually introduced until a full size is obtained. The process generally occupies from ten to thirty minutes, according to the resistance, care being taken not to tear, and so cause hemorrhage. I then withdraw the dilator, and pass a catheter, for the purpose of removing any urine that may be there. I usually give a dose of Fleming's tincture of aconite immediately after the stretching has been practiced, and require the patient to remain in the house for twenty-four hours. A full sized bougie is then passed every third or fourth day, until the patient has learned how to conduct this operation himself, when he must be enjoined to continue this practice.

It will be seen that this proceeding differs essentially from what is so well known as Holt's operation. In the one, the object to be attained is stretching; while in the latter it is rupture. It is the only plan of treatment by which the strictured urethra is at once brought up to a full capacity, without break of tissue.

In conclusion, I would remark that I am not recommending this as a panacea, or as prejudicing other proceedings to which reference has been made; but as a safe and efficient expedient for meeting immediate difficulties, and simplifying future treatment. If, in all cases of retention occurring with tight stricture, the use of this or a similar instrument followed the passing of the catheter, both patient and practitioner would be none the worse for the knowledge that, whatever spasm might temporarily do, at all events there was a way to the bladder which had been made without any structural detriment, capable of admitting a No. 12 bougie. The dilator, as adapted for this purpose, was shown by Messrs. Krohne and Sesemann, in the International Medical and Sanitary Exhibition.

Malignant Disease vs. Syphilis.

In the *British Medical Journal* Dr. Alexander Patterson, of Glasgow, says:—

"Every surgeon, I am sure, reads with pleasure and profit anything from the pen of Mr. Jonathan Hutchinson. In the *Journal*, of March 4th, he refers to the clinical differences in character of malignant disease, according to its seat. Referring to certain cases of cancer of the skin of the trunk, it is stated that, "In all, the ulceration progressed slowly during many years, caused but little pain, and produced no gland disease." Further on: "The disease of which I speak is most intractable, and, as far as I have observed, recurs immediately after removal." Reference is next made to an interesting case, in which Mr. Hutchinson twice removed the ulcer by the knife, and three or four times by caustic, but without benefit. "As soon as the sore was nearly healed it recurred."

May a provincial surgeon be permitted to give a case in many respects parallel? Some years ago, a man aged 45, suffering from epithelial cancer of the scrotum, sent for an eminent surgeon, for the purpose of having it removed. The operation was well performed. No one who saw the case had the slightest misgiving regarding

its nature, but, as a formal matter, the diseased structure was handed to a practiced microscopist in the neighborhood, who stated that it was epithelioma, without doubt. When nearly healed, it recurred, and was removed again, only to begin to spread when almost completely well. A third time it was taken away, with a like result. At the fourth operation, the testicle, which now appeared to be implicated superficially, was removed. When cicatrization was all but perfect, the surgeon left town for his holidays, and shortly afterward the patient's medical attendant requested me to perform the fifth operation, as the disease was spreading again. Having the history of the case before me, in a hopeless, half-hearted sort of way, I cleared away the diseased tissues as carefully and completely as possible with the knife, and watched the healing process with much interest. Matters progressed very favorably until the healing line was reached, when once more the ulceration began. Such conduct in a chimney-sweeper's cancer appeared to me unique. I saw that operating again was useless, and as I stood pondering at the bedside, my eye rested on the shining bald head of the patient. As a random shot, the question was put as to when his hair first came out. He said his hair began to fall soon after he joined the service, more than twenty years ago. The answer gave the clue. Iodide of potassium was prescribed, when the wound rapidly and perfectly healed, and has so remained.

Last year a lady, aged 60, came to consult me regarding an ulcer on the left side of the nose. She had been recommended by her medical attendant, whose card she brought, to see me regarding removal by operation. The sore, she said, began about two years ago, as a small scab or flattened wart, and continued to increase in size, slowly and without pain, since that time. The ulcer was now about five-eighths of an inch in length by half-an-inch in breadth, throwing out little discharge, and surrounded by an elevated, clear, glistening border. As she was accompanied by a friend, few questions were asked, and I simply stated that it might be prudent to defer operative interference in the meantime. The patient was given a prescription for tertiary syphilis, requested to use the medicine for six weeks, and then return. She did so, and the sore was completely healed. This was apparently a small rodent ulcer, with a syphilitic origin. We are, probably, yet far from thoroughly understanding the multifarious ramifications of syphilis.

Antiseptic Ligature of Arterial Trunks.

At a recent meeting of the Clinical Society of London, *British Medical Journal*, May 6th, 1882, Dr. Hector C. Cameron, of Glasgow, read notes of all the cases of antiseptic ligature of arteries in their continuity in which he had performed such an operation, whether for aneurism or for accidental wound. The material employed was antiseptic catgut (prepared by one or other of the methods suggested by Mr. Lister), of medium size, and tied in a reef-knot, with sufficient tightness to ensure division of the internal and middle coats of the vessel. Very accurate coaptation of the cutaneous margins of the wound was practiced by stitches of carbolized silk or silkworm gut, with an occasional stitch of thick silver wire, for purposes of relaxation, where that seemed desirable. Free drainage was effected by means of india-rubber drainage tubes in all the cases except one, in which a number of strands of carbolized catgut were employed. The operations, as well as the subsequent dressings, were conducted with rigid antiseptic precautions.

After describing the cases minutely, he said: In these five instances of aneurismal disease, six large arteries were ligatured. In each, complete and permanent occlusion of the vessel was obtained, without any constitutional or local disturbance, without any rise of temperature (if the case of diffuse popliteal aneurism during the first six days be excepted), and without the formation of a single drop of pus. In each case the last dressing was applied respectively on the fourteenth, tenth, eighth, eleventh and twelfth days after the operation; and in each, on the removal of that dressing, the wound was discovered to be thoroughly sound. On similar principles, the radial artery was ligatured four times, the ulnar artery twice, and the popliteal artery once, with equally satisfactory results. In the last case, however, the anterior part of the foot lost its vitality, and ultimately required amputation. The vein, as well as the artery, was injured by the wounding instrument.

Mr. R. Godlee said that in almost all these cases related by Dr. Cameron ligature of the artery was the only possible treatment. It seemed to him now that as treatment of aneurism by digital pressure, the tourniquet, Esmarch's bandages, flexion, etc., was usually very irksome and painful, it might possibly be well to treat all cases at the first by ligature with carbolized catgut, which, as now prepared, kept its hold of the vessel a sufficient length of time to ensure its occlusion.

The President said that Dr. Cameron's experience coincided with his own in so far as this, that the old-fashioned carbolized catgut fulfilled its purpose if properly prepared, and the treatment was thoroughly antiseptic, except in cases where a very long continued pressure of the vessel by the catgut was necessary. But the catgut should be as strong as silk, as soft as the normal tissues; it should be capable of retaining a knot on it with perfect security, and should be free from porosity, so as not to hold organisms in it, as did silk. But, however nearly perfect the ligature might be, there was no use in it unless perfect antiseptic treatment was also adopted, because, otherwise, the outer coat of the artery must die, and suppuration ensue. He believed this was the reason why Dr. Cameron's treatment was so universally successful, he having strongly insisted on the antiseptic treatment in its entirety.

Dr. Cameron, replying to Mr. Godlee, said that Esmarch's bandage had been first tried in the two cases of popliteal aneurism, but the agony was intolerable after some minutes, and each patient could endure no more. The ligature was then used with success. In two cases he had seen no benefit follow pressure, and his surgical colleague, going by his (Dr. Cameron's) experience, had then ligatured the femoral artery in Hunter's canal. When compression was tried, and the collateral circulation thereby established, one might find a second ligature even

necessary, as in one of these two cases, in which the artery was tied in Hunter's canal, when the ligature at the apex of Scarpa's triangle had failed. He believed that as the treatment by the ligature was so free from risk, it was better practice to adopt it at once than to try earlier treatment by these other methods, which were irksome, and interfered with the chances of successful treatment by ligature should it become necessary.

Tracheotomy.

The *Lancet*, April 26th, 1882, says:—

A case related by Dr. Felix Semon, at the last meeting of the Pathological Society of London, presents several points of great importance to physicians and surgeons. But the one to which we wish to direct attention is the fact it illustrates, that a double obstruction of the air passages may exist, and one of them be undetected and unrelieved by operation. In this case there was paralysis of the glottis-openers, and for this tracheotomy was performed, but failed to give relief; and it was subsequently found that a tumor was pressing upon the trachea below the opening in the tube. This tumor was so small that it could not be recognized during life. Other cases of a like nature have been met with, in which a tumor or aneurism has, by direct pressure, and also by implication of the recurrent laryngeal nerves, caused obstruction to respiration, and if an operation has been undertaken in accordance with the view that the laryngeal obstruction is the whole respiratory trouble, only disappointment has resulted. It is impossible in many cases to recognize this condition; the paralysis of the posterior crico-arytenoid muscles quite prevents inspection of the parts below, and in all cases the surgeon is warranted in operating, but should caution his patient that there may be some deeper obstruction to respiration than that which his operation is intended to overcome.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received a copy of the "Addresses at the Inauguration of William Pepper, M.D., as Provost of the University of Pennsylvania." This is a valuable pamphlet, containing, as it does, the history of a very important date in this old institution.

——"Higher Medical Education," a reprint from the Penn Monthly. This is the valedictory address delivered by Professor James Tyson, at the last commencement of the University of Pennsylvania. This address, containing the experience of the University of Pennsylvania in its struggle for higher medical education, and depicting in glowing terms its glorious triumph, is well worthy of perusal by all.

——We have received the Report of the Indiana State Board of Health. With this report we receive a copy of an address, read before the Mitchell (Ind.) District Medical Society, by Thad. M. Stevens, M.D., on the "Essentials of a Law to Regulate the Practice of Medicine in Indiana." It is full of good points, and we sincerely trust that the profession of Indiana will succeed in getting the legislation they desire.

——Ovariotomy, difficulties, diagnostic and operative; continued menstruation, after double ovariotomy. A reprint from the *American Journal of the Medical Sciences*, April, 1882. The author deprecates routine Listerism in this operation, saying, "cleanliness, not carbolic acid, is necessary. Keep sponges clean and warm, but *not* carbolized. Avoid carbolic acid about the peritoneum and open surfaces. Ligatures, sutures and instruments should be clean, but not carbolized."

BOOK NOTICES.

An Index of Comparative Therapeutics; with Tables of Differential Diagnosis, etc. etc. By Samuel O. L. Potter, A.M., M.D. Second edition. pp 280. Chicago: Gross & Delbridge, 1882.

This is an effort to prepare a volume containing the therapeutics of the drugs used by the regular profession, as well as those in use by the homœopaths. Just what practical benefit will be derived from such an exposition we are unable to see. But the book is well prepared, and possesses some interest from a literary and curious standpoint.

Manual of Diseases of the Skin, with an Analysis of eight thousand consecutive cases and a formulary. By L. Duncan Bulkley, A.M., M.D. pp. 312. New York: G. P. Putnam's Sons. 1882.

Dr. Bulkley has well earned the right to be considered an authority on diseases of the skin; and since such diseases have become so very common, it is really necessary for all physicians to have some knowledge of them. Specialists are not to be found everywhere, but skin diseases are, and they are in many cases extremely difficult to cure. This manual will be found extremely useful to every general practitioner.

A Manual of Obstetrics. By A. F. A. King, M.D., Professor of Obstetrics and Diseases of Women and Children in the Medical Department of the Columbian University, Washington, D. C. pp. 325. Philadelphia: Henry C. Lea's Son & Co. 1882.

This manual will be found useful by the busy practitioner, for two reasons: 1st. The instructions and advice it contains are intelligibly given, and so arranged as to readily be found when wanted. 2d. The book is small and of a shape convenient to carry about. By its use the practitioner may often be enabled to relieve himself from very embarrassing situations. The book is well illustrated and contains a complete index

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

DIGITALIS AND ACONITE.

Modern science has unquestionably settled many formerly doubtful points, and while, perhaps, for many years to come, empirics will have to guide us to a great extent in therapeutics, physiological observations based upon experimental research will finally bring order out of chaos, and give us the why and the wherefore. This is nowhere more apparent than in the two great remedies by which we influence the action of the heart, digitalis and aconite. There are still many physicians who cannot see the great results gained by physiological experiments with drugs; let them compare a work on materia medica published twenty years ago with one of our time, and their eyes will be opened. What did we know formerly of digitalis and aconite? That they were remedies by which we might reduce the action of the heart and lessen the frequency of the pulse. But observations were published giving seemingly very antagonistic results. One report would show that aconite, instead of reducing the pulse really accelerated it, while a physician of equal repute would relate a case where this remedy undoubtedly diminished the number of beats. Similar contradictory observations were made of digitalis. Who threw light on the subject? Those patient investigators, who, with the aid of all modern means of research, carefully watch the action of drugs on lower animals and scrupulously note the effect on blood pressure, etc., guided us out of the labyrinth and gave us the definite indications for the use of these remedies.

And what is the result of their experiments? They have proven that digitalis is a tonic for the heart; that under its use the contractions of the organ become more powerful; that in consequence the frequent and weak pulse becomes slower and fuller, and that this remedy should, therefore, be employed, when the rapidity of the pulse is due to debility of the main organ of circulation and the blood pressure is diminished. They have further demonstrated, that the effect of aconite is exactly the opposite; that this remedy reduces the strength of the impulse; that in cases of overaction of the organ, of too powerful contractions of the same, it diminishes the frequency of the pulse and reduces the blood pressure. We can now see the reason why, in some cases of acute croupous pneumonia, digitalis is the safer remedy, and in others aconite or veratrum viride, the latter being very similar in its effect to aconite. If a strong and robust adult, with a vigorous heart, is affected with pneumonia, our aim, in the beginning, must be to reduce the strength of the heart, and of the blood pressure, not to increase it, and we administer aconite or veratrum viride with happy results. In such a case the remedies named will diminish the frequency of the pulse. But if an anæmic individual or an old person with a weak heart is suffering from pneumonia, and we should employ the same means, the heart would become weaker still, and the pulse at the wrist more rapid. Here digitalis will give tone and strength to the heart; under its influence the latter will contract with more vigor, and the pulse will be diminished in frequency.

It would lead us too far, were we to give every indication for the use of digitalis or aconite; but

this rule can always be followed with safety: Whenever we wish to reduce the arterial tension and the power of the heart, when we aim to weaken the latter, aconite is the remedy indicated; while to increase the strength of the organ and the activity of the circulation, to diminish the frequency and improve the tone of the pulse, we have to employ digitalis. Therefore, in organic diseases of the heart, aconite is beneficial in hypertrophy, and digitalis in dilatation.

SALICYLIC ACID.

While experience has proven that salicylic acid does not diminish the dangers of acute articular rheumatism—the percentage of heart complications, if we can rely upon statistics published, being rather higher since the use of this medicine than under the former alkaline treatment—the remedy is as near a specific in this disease as we will perhaps ever possess. But it should be given in large doses, and frequently enough. If correctly administered, it will invariably reduce the temperature, lessen the severity of the inflammation and swelling, palliate, not only the excruciating pain, but totally remove the latter in the majority of cases, and lastly, decidedly shorten the duration of the disease. Of this we have often, in private and hospital practice, the opportunity to convince ourselves. There are still many physicians who either have not as yet used this remedy at all, or did not succeed in gaining the results mentioned. Such physicians generally hesitate to push the treatment, because they are afraid, and dread the collapse about which so much has been written. But while the practitioner has frequently been cautioned not to push the remedy till the collapse takes place, and, to make matters worse, while it has been said that such accidents may happen suddenly, no sign has been given by which the less experienced physician might know when to stop. A long acquaintance with the drug has convinced us of the truth of the following assertions:—

(*a*) Salicylic acid or its combinations can be given to an adult suffering from acute articular rheumatism, in doses of twenty grains every two hours, without any danger, *as long as the pulse does not beat below* 84 *in a minute.* Whenever the pulse falls below 84, the dose has to be decreased to ten grains, or, still better, the frequency of the original dose is diminished, say every four hours or three times daily, instead of every two hours. Should the symptoms again become worse and the pulse increase in frequency, the physician can without any risk administer the drug the same way as at first, and continue it again, till either there is no more necessity for such large doses and their frequent repetition, or the pulse begins again to drop below 84; amelioration of the symptoms and decrease in the pulse rate going hand in hand.

(*b*) Instead of giving salicylic acid alone, the following combination acts better and—if the first rule be observed—is safe, even in cases of pre-existing organic heart lesions, and seems decidedly to lessen the danger of endo- and pericarditis arising as complications:—

℞. Acidi salicylici, ℥ ss
Liquor. ammoniæ acetatis, f℥ ij
Aquæ destillat., f℥ iij
Syrup. cortic. aurantii, f℥ j. M.
Sig.—A tablespoonful in water every two hours.

If this combination is prescribed, and the first rule followed, our readers will find that, in cases of acute articular rheumatism, the effect of salicylic acid mentioned above will invariably take place, but collapse never happen.

Notes and Comments.

Cesspools.

From the *Sanitarian* we take the following very pertinent remarks: Cesspools and privy vaults are the bane of the country; the perennial hot house of scarlet fever, measles, typhoid fever, diarrhœa and dysentery, and the exciting cause of many other diseases. But country house privies, odious as they are, are insignificant as compared with what Professor Frank H. Hamilton, in his paper before the New York Academy of Medicine, so significantly designates, "Dangers of Æstheticism," if applied to hidden city vaults, school house cesspools, æsthetic *new* villages, villas and fashionable country resorts "for health." For the old-fashioned country-house vault, light and air, aided by the sense of smell, do something toward lessening dangers. But the

æsthetic vaults and cesspools common to fashionable new villages, schools and summer resorts, are hidden away in dark corners, or excavated and carefully covered, even turfed over, lest the beauty of the lawn be marred. Carefully hidden, as the viper or the sneaking assassin, and supplied with all the conditions of potency—darkness, warmth, moisture and ferment—the conditions are complete for the development and self-multiplying of disease poisons, call them germs or what you may, to an illimitable extent. For the *old* country-house privy there may be some excuse for its construction, but in the light of present knowledge, those who tolerate them might learn wisdom from the cats; but no time should be lost on the obtuseness of those who will not learn.

All such sources of disease should be indicted and removed as common nuisances, and to build one be made a criminal offence.

Rupture of the Œsophagus.

At a recent meeting of the Royal Medical and Chirurgical Society (*British Medical Journal*), Mr. Stanley Boyd related a case in which the œsophagus had ruptured into the right pleura. The patient was an infant, aged four months, who had been exceedingly ill for some weeks before death, with erysipelas followed by peritonitis, which had followed an operation for strangulated undescended testicle. About two hours before death dyspnœa suddenly set in, and lasted for an hour. When the dyspnœa passed off the child was able to take food in small quantities, but while it prevailed it choked when given brandy and milk. At the autopsy, about one ounce of clear, deeply blood-stained fluid, free from lymph or any trace of milk, was found in the right pleura; both lungs were partially collapsed, the lower and middle lobes on right side were very red, and were studded with petechiæ; and at the root there was a considerable sub-pleural hemorrhage. The pleura was absent from the œsophagus over the whole of its right side, below the root of the lung, and its torn edge could be easily seen near the diaphragm. Pressure on the œsophagus caused a bubble of air to escape through a small opening in its wall; on the inner aspect of the gullet several small blood-clots were found near the hole referred to; this measured about two millimeters, and for a short distance above and below, the circular muscular fibres were exposed. Mr. Boyd considered that the clots in the gullet, the bloody fluid in the pleura, the marked redness, and numerous petechiæ on the surface of the lung, proved that the perforation took place during life, and that, possibly, it had been the cause of the dyspnœa which set in a few hours before death.

Arsenical Treatment of Chorea.

M. Siredey, we read in the *Revue de Thèrap. Méd. et Chirurg.*, has long had recourse to arsenic in the treatment of rheumatismal chorea, and has had good results from this medication. He uses the solution of Bondin:—

℞. Ac. arsenious, gr. xv
Aquæ destill., Oij. M.

This is allowed to boil for about a quarter of an hour, and is then ready for use. The extreme dilution of the solution is favorable for its use among children. For a child from six to ten years of age, about one drachm and a half may be given daily, in divided doses, in sweetened water. In this way the medicament is generally well tolerated.

Dr. Sottmann, of the Breslau *Clinic*, constantly prescribes the following solution in chorea:—

℞. Liquor Fowleré, ♏iv
Aquæ, ʒij. M.

This quantity to be taken in divided doses daily. He generally obtains a complete cure in from 16 to 21 days.

In some cases he adds from 8 to 15 grains of chloral to the prescription. He has generally found that anæmic children, and those of hereditary nervous dispositions, bear this form of medication well.

The Chemical Cause of Life.

Up to within a very few years, physiology did not suspect that there was any chemical difference between dead and living protoplasm. Many still will say there is none. But recent researches, beginning by an article of Pflüger's in 1875, point strongly in an opposite direction. One of the ablest essays in the affirmative was written last year, by Dr. Oscar Loew (well known in scientific circles in this country) and Dr. Thomas Bokorny, and published at Munich, with the title *Die Chemische Ursache des Lebens theoretisch und Experimentell nachge, wiesen*, pp. 51. The result of their investigation goes to show that living protoplasm owes its property of *life* to the presence of aldehyde groups, which are characterized by intensely active atomic movement. When death takes place, it is coeval with and caused by a transformation of these aldehyde groups into amyd groups, with diminished molecular motion, thus leading to cessation of action.

The thoughtful reader will not fail to note the very great importance of this physiological theory,

and we can say that it is supported by a series of admirably careful experiments. We earnestly commend the pamphlet to American physicians. It is published by J. A. Finterslin, Munich, and can be obtained through any importer.

Laryngeal Anæsthesia.

The *Lancet* says, editorially—

The sensory branch of the superior laryngeal nerve enters the larynx through the thyro-hyoid membrane, below the rounded extremity of the cornu of the hyoid bone. At this spot the trunk of the nerve is not far from the surface, and Rossbach has proposed to render the larynx insensitive by injecting near this nerve, on each side, a small quantity (five milligrams) of morphia, with the intention of destroying the conductibility of the nerve. The proceeding was perfectly successful. He afterward ascertained, by experiments upon healthy persons, that the conductibility of the nerve might also be interrupted by a considerable degree of cold. He therefore employed Richardson's ether spray apparatus, directing a jet on each side of the neck simultaneously. The application for two minutes sufficed to render the larynx insensible to the presence of a foreign body. The method is suggested as likely to be useful in reflex spasms originating in the interior of the larynx. It is possible, also, that the facts afford an explanation of the unquestionable utility of the application of ice to the exterior of the larynx in some cases of spasmodic croup.

Imperforate Hymen.

Dr. W. G. Moore says, in the St. Louis *Clinical Record*, that a young girl of seventeen called at his office with symptoms of a malarial attack, for which he gave her appropriate treatment. Three days later he was called to see her, and upon entering the room found her screaming with pain. The mother said that the fever had "settled in Lizzie's womb." Every few minutes she would have a very severe pain in every way simulating labor pains. On attempting to introduce the finger into the vagina, it was met by an elastic tumor as large as the vertex of the ordinary fœtal head, and having exactly the feel of the protruding membranes when about to rupture. Further inspection revealed an exceedingly thick and resisting imperforate hymen. This was punctured with a bistoury, when, by the aid of a grooved director, the incision was enlarged to the full size of the vagina. The after treatment consisted in rest in bed, and carbolized injections. The retained blood in this case was at least a quart.

A New Fungus.

The *Gazette Médicale* states that M. Pasteur has found an organism in the blue and green discolorations which are sometimes seen on old surgical bandages, which preserved through many cultivations the same characters and properties. It consists of colorless globular cells, from $\frac{1}{1000}$ to $\frac{5}{1000}$ of a millimeter in diameter, and has the power of secreting a pigment, which may easily be dissolved out by chloroform. The blue, or pyocyanine is reddened by acids, and restored by alkalies. Dissolved in a weak acidulated solution, neutralized by potash, and treated again with chloroform, pyocyanine yields a pure blue liquid, from which, after evaporation, it appears in the form of crystals, sometimes as prisms or matted needles, at others as rectangular plates. The watery solution of pure crystalline pyocyanine is neutral, and is unchanged by boiling.

Arsenical Poisoning from Sardines.

Dr. P. S. Jenkins, in the *Medical Herald*, reports the following: He was called to see two patients, whom he found vomiting and purging violently, with pain at the epigastrium, intense thirst, dryness of fauces, extremities cold, shivering, chilly, pulse scarcely perceptible and very rapid, respiration belabored, great agitation and restlessness, intellection good. Under the following treatment they both recovered: Milk and eggs to protect mucous membrane: hypodermic injections of sulph. morph. and atropia, quinine; carbonate of ammonia and whisky were given as cardiac stimulants, and dialysed iron as a physiological antidote. They had both eaten sardines and oysters. Upon examination, the sardines were found to contain a large quantity of arsenic.

Pet Animals as Carriers of Contagion.

The *Sanitary News*, calling attention to this danger, says: The contagious feature of some diseases has been disputed by the incredulous, because no channel of communication could be discovered between the first and subsequent cases. Dr. William Bunce, of Oberlin, Ohio, reports a case in which five children of a family of six were taken with diphtheritic sore throat, no source of contagion being discoverable about the premises. A cat in the barn was found to have the characteristic lesions of diphtheria, and inquiry elicited the fact that the cat had been

fondled by the children during its illness. A few months later this same observer lost a patient from diphtheria, who had a few days before charitably removed some obstruction from the throat of a pet cat, which, upon examination, was found to be diphtheritic false membrane. In these instances the cats were made the carriers of the contagion by contracting the disease, either from some preëxisting case among animals of their own kind, or among people who petted them, or it may be from some unsanitary surroundings.

A Rare Affection.

M. Niellé, naval surgeon and professor of colonial pathology at Brest, has observed a papular eruption on a cabin boy of fourteen years of age, which is peculiar in character, and cannot be mistaken for either scabies or eczema. It resembles an affection called crawcraw, which exists among the negroes of the New Guinea coast. Microscopical examination of the serosity of the papules brought to light the presence of nematoid worms, similar to filariæ, in different degrees of development, from the adult and sexual stage, down to the embryonic. In the embryonic stage they are found in the blood. This affection is not contagious. It is believed that the filaria enters the animal economy by means of the water imbibed. In the adult stage the worm is one-third of a millimèter long, and one-hundredth of a millimèter in diameter.

Paronychia Gangrænosa.

Mr. Croly presented two specimens of this disease to the Pathological Society of Dublin (*British Medical Journal*). Both patients were middle-aged ladies, and in both the seat of disease was the inguinal phalanx of the first finger of the right hand, which phalanx at last separated. One of the initial symptoms was severe pain, like the stinging of nettles, in the end of the finger; vesicles then formed, which passed into unhealthy bullæ.

Pericarditis in Uræmia.

M. Keraval, in a recent memoir, has made an interesting study of the variety of pericarditis sometimes observed in Bright's disease.

From his researches it seems to occur most frequently in interstitial nephritis, and is even then rather rare. It is always in the last period of the disease, generally after the development of uræmic symptoms, that it appears. It is constituted by a neo-membranous inflammation, terminating sometimes by adherence of the layers of the serous membrane. Generally there is no liquid effusion, or it is in very small quantity. As it is not accompanied by endocarditis, the pericarditis often passes unperceived unless the heart is examined, when the usual physical signs are found. It is generally of grave prognosis, as the patient soon succumbs to the uræmic symptoms.

M. Pasteur's Discoveries.

The *British Medical Journal* says: An application to man of M. Pasteur's researches on the preservation of animals from malignant pustule has been reported by M. Casson. in a note read at a meeting of the Acadmié des Sciences. He described the case of a farmer who had been twice attacked by charbon, The first attack was slight, the second was very serious and expected to be fatal. However, the dangerous symptoms speedily disappeared, leaving two deep ulcers on the back of the hand. M. Casson considers that the rapid improvement indicates an actual vaccination resulting from the first attack of charbon, and suggests that the case confirms the facts established by M. Pasteur's researches on the preservation of animals by the inoculation of attenuated virus.

Sarcoma of Tonsil.

At a recent meeting of the Pathological Society, of London (*Medical Press and Circular*), Dr. Samuel West presented a specimen removed from a woman, aged seventy-four years, who had come under his care for "sore throat." The right tonsil was the seat of a large tumor; it was rapidly increasing in size, and displacing, but not invading, the tongue and adjacent structures. She died within five months of its commencement. The lymphatic glands of the neck were all much enlarged. A large secondary growth was found between the spine and the spleen, and smaller ones elsewhere. Microscopically, the tissue was found to be a small round-celled sarcoma.

Congenital Teeth.

Dr. F. B. Harrington reports the following case in the Boston *Medical and Surgical Journal*:—

Two small white spots were accidentally noticed on the lower jaw of a child, then twelve days old. The spots were supposed to be thrush. Four days later the mother complained that the child caused her great pain in the nipples while nursing. An examination of the mother's breasts did not show adequate cause. On looking into the child's mouth the two spots were found to be two sharp-edged incisor teeth. They were removed, and appeared to be the right central and right lateral lower incisor.

Special Reports.

NO. VI.—MICRO-GERMS.*

BY DR. W. F. MUHLENBERG,
Of Reading, Pa.

The science of medicine, like its sister sciences, has been eminently progressive in its character. Each new advance has contributed to the removal of disease, the diminution of human suffering, the prolongation of life, and the increase of the happiness of mankind; and we may reasonably hope, from the past history and present condition of medicine, for a like progress in the future. Our knowledge of disease and its removal has not yet reached perfection, and as long as this is not the case, there is ample room for continued investigation.

In harmony with this view, I have selected for the present occasion the subject of micro germs. It is true our knowledge of these germs is yet in its infancy, and we cannot accurately estimate their importance in producing disease. Yet the subject is one of such great extent, and seems to be so intimately connected with the manifestations of disease in the human system, that it has appeared to me advisable and useful to present some of the many interesting facts and observations with reference to these germs, and the proper methods to be pursued in propagating and preserving them. This seems to be the more necessary because the knowledge of them is not easy of access, often being of a fragmentary character, and scattered in many publications.

The only work, so far as my knowledge extends, to be found in this country, on the subject of "Bacteria" or germs, is a translation by Dr. Sternberg, U. S. A., of a French work on the subject, by Dr. Magnin, and to this we especially refer all those who are interested in the study of these germs in their botanical peculiarities.

Before proceeding with our subject, we may remark, that every physician of the present day ought to possess a microscope; for, by following the methods of examination heretofore proved to be scientifically accurate, or discovering new scientific processes of investigation, he may succeed in solving problems which hitherto have escaped solution, or find out new facts which may be of incalculable benefit to the human race. The researches of Pasteur, a single individual, it is said, have been of more service to France than the milliards paid to Germany. The possibility that some of our infectious diseases, by a process of vaccination, may be rendered harmless, is sufficient to attract workers in that direction; and though the results thus far may seem to be insignificant, they ought not to be discouraged by the sneers of others, but patiently continue their labors, with the hope of ultimately obtaining more accurate knowledge upon the subject.

The only direct test for germs is the peroxide of hydrogen, $H_2 O_2$, but as it is split up into oxygen and water, by numerous metals, and also by the red-blood corpuscles, it is of an unreliable character. The products of the fermentation, degeneration, and putrefaction of germs, such as ammonia, sulphuretted hydrogen, leucin, tyrosin, indol, phenol, skatol, cresol and paracresol, phenylpropionic and phenylacetic acids, can be more readily detected. The pancreatic fermentation decomposes albumen into leucin, tyrosin, and similar bodies; but indol, skatol, phenol, and cresol, are ordinarily found in the large intestine. The coats of the large intestine seem to be endowed with a great capability of resistance to germs and their products; and while these bodies appear to be unable to enter the system through the lower bowel, the marks of their entrance, in the shape of ulcers and colonies, are always found in the small intestine, particularly in the neighborhood of the ileo-cæcal valve. Sulphuretted hydrogen, (1) always present in the large intestine, in larger or smaller quantities, has been proved to have passed through the coats of the small intestine, and to have been excreted through the kidneys; and this shows that products of decomposition can only enter the system through the upper portions of the bowel. The excretions of the intestinal canal of new-born infants do not contain the higher products of albuminous decomposition, as indol and skatol, and, as has been frequently proved, no germs. *

All these products (2) appear to be removed

* Read before the Pennsylvania State Medical Society at its annual meeting, at Titusville, May, 1882.

* The tests for leucin, $C_6 H_{13} NO_2$, are as follows: If a fluid suspected of containing it is evaporated in a platinum dish, with a small quantity of nitric acid, there will be left a colorless, almost invisible residue, which, when heated with a little caustic soda, becomes yellow or brown, as the leucin happens to be pure or impure; and, on further concentration, changes to oily-like drops, which move freely around the dish without adhering (Scherer's test). When this substance is dissolved in a boiling solution of lead-acetate, on the addition of ammonia to the cooled solution there will be a separation of shining lamina, consisting of a mixture of leucin and plumbic oxide, from which the leucin can be subsequently sublimed, in wooly masses.

The tests for tyrosin, $C_9 H_{11} NO_3$, are as follows: Add to the suspected fluid, diluted with some water, a solution of the acid nitrate of mercury; then boil for some time; if tyrosin is present, the solution, at first, will exhibit a beautiful rose-red color, and subsequently, a red-precipitate (Hoffman's test); or, pour a few drops of concentrated sulphuric acid on the fluid, heat it moderately, when it will dissolve with a faint red color. If water and barium carbonate be added until effervescence ceases, on evaporation and filtration, the addition of a few drops of a neutral solution of ferric chloride will give rise to a violet color (Peria's test).

as so-called ethylsulphuric acid. Phenol or carbolic acid, in addition to a number of intermediary products, seems to be derived from tyrosin, or, more probably, comes off as a paracresol.

Indol, $C_8H_7N_7$ melting at 52° C., and skatol, either C_9H_9N, or $C_{10}H_{11}N$, viewed as a methyl-indol and melting at 95° C., are two of the most important products of albuminous decomposition, as their presence almost invariably indicates germs.

The presence of skatol with indol changes somewhat the result of the ordinary test for indican in the urine (it is necessary to add to the urine an equal quantity of hydrochloric acid, and of a saturated solution of chloride of lime, or chlorinated soda), for, if indol alone is present, the fluid becomes green or blue, but if skatol is in excess, it becomes violet or red. Indol passes over into the urine as the indoxysulphate of potassium. There is a marked increase of indol in dyspepsia. gastro-duodenitis, chronic constipation, intussusception, diarrhœa, cholera and typhoid fever, while phenol is apparently increased in peritonitis and miliary tuberculosis. Jaffe found that the tying of the small intestine caused an increase of indican in the urine ; and the same result was produced by a prolonged and exclusive meat diet. Skatol gives with dilute nitric acid a pale violet color, and with fuming nitric acid a red flocculent precipitate (Nencki's test). Skatol (3) besides, is less soluble in water, and is not discolored by the addition of chlorine water. Dr. Wernich (4) who has made a special study of these products of albuminous decompo sition, lays down two general principles: Firstly, "That the bacteria themselves prepare the conditions for their destruction;" and, secondly, "That very slight quantities of the poisons so generated protect against infection by new organisms of the same variety;" and he believes that these germs cease to increase, not on account of a deficiency of oxygen or nutriment (although many germs are anærobiotic), but because of the generation of some bodies of this kind which occasion antisepsis instead of putrefaction. The fact that the products of decomposition of the germs artificially cultivated do not smell of indol or skatol (so-called from the Greek word σκῶρ, gen. σκατός) proves almost conclusively our inability as yet to solve the life problems of these germs; nevertheless it does seem remarkable that a body like carbolic acid, one of our best antiseptics, should be a natural product of the decomposition of albuminous bodies in the intestines. Phenylacetic acid, C_6H_5COOH, C,H_2, or $C_8H_8O_2$, and phenylpropionic acid, $C_6H_5CH_2CH_2COOH$, or $C_9H_{10}O_2$, bodies analogous to benzoic acid, but as yet insufficiently known, and phenol and cresol, two bodies well known, make up the list of bodies resulting from the decomposition of germs.

In the microscopic examinations, the various appliances used should be in a state of absolute cleanliness, on account of germs in the various fluids used, and from the constant presence of spores in the air. Micrococci and bacteria (5) have been found even in a two per cent. solution of carbolic acid, as well as in distilled water and various hypodermic solutions, but cannot be found in perfectly fresh solutions of carbolic acid, which seems to lose its efficacy as an antiseptic after exposure to the air. From experiment at Montsouris, in France, it was shown that during the warm months there was an average of 28 spores in each litre of air, while during the winter months very few could be found. On the contrary, after a long continued rainfall, nearly 100 spores were found in each litre, and the air of rooms was always more deficient in them than that outside. Distilled water, which has been thoroughly boiled, should be used in all the investigations. All the glass ware should first be cleansed with some strong mineral acid (sulphuric acid and a solution of bichromate of potash answering very well), then well washed with distilled water, and subsequently purified with absolute alcohol, the remains of which should be burned out, or the glass passed through the flame of a Bunsen burner. Any metallic instruments, used for applying a deposit on a slide, or for other purposes, should be passed through a flame, and, where possible, used in a heated condition. Keeping the various instruments for some time in a hot air bath, or an incubator, at a temperature of 100°–120° C., will be found almost necessary. After the culture fluids have been prepared and sterilized, a compact wad of cotton, which has been heated to 135° or 140° C. will serve to cover the test tubes and prevent the access of spores. It is not necessary, and, in fact, it is disadvantageous, to carbolize such wads, as the presence of carbolic acid may keep the germs from growing.

Germs may be confounded with blood corpuscles, fat globules. epithelial cells and their nuclei, leucocytes, mycelial threads, vibrios, coagulated fibrin, granular crystalline deposits, granules of casein, particles of fibres, wood, feathers, etc., and air globules. and possibly, the small granules spoken of by Howlett (6) which, 2.5 to 4 m. long, arrange themselves in racemes and can be stained with methyl-violet.

Forms (7) whose thickness does not exceed 1 m. cannot, in general, be distinguished from inorganic bodies of like size and form. Crystalline bodies, which have double refraction, may be recognized by the polariscope, as germs have only single refraction. If granules possess continuous motion, particularly in a straight or curved line, they are certainly schizomycetes or monads, while molecular motion gives no positive decision. If the granules arrange themselves in pairs or triplets, and, particularly, if they show a true spherical or oval form, they are organized. If bacilli seem to be present, and if they present a knee-shaped curvature, they are also organized. "In zooglœa forms (8) the micrococci of an individual zooglœa mass are always uniformly of one size, and are always at the same distance from one another, in contradistinction to albuminous and fat molecules." Fat and most other molecules are soluble in alcohol, liquor potassæ, ether, strong acids and alkalies. Pus and epithelium are dissolved by caustic potash, while inorganic and many organic bodies are destroyed by the strong acids. The granular mass (9) is insoluble in acetic and hydrochloric acids, caustic potash, glycerine, chloroform, and oil of cloves; ammonia makes germs more colorless, but dissolves pus, while liquor potassæ, with a subsequent addition of iodine, colors the germs brown. Cultivation is the best mode of purifying and distinguishing the germs.

The germs are best examined by the dry method (10) which consists in allowing a thin layer of the fluid containing them to dry on a slide, under a cover glass, and subsequently softening and staining it for examination. The substance should be spread in a thin layer, so that greater or less interspaces lie between the objects, and then allowed to dry under cover, so as to prevent the admixture of other spores. Such dried slides can be preserved, even for months, under a bell-glass, and then softened. Water and glycerine loosen the germs from the glass, but absolute alcohol, and a half per cent. solution of chromic acid renders them insoluble, but hardens them so much that they often lose their natural form. Acetate of potash (aqua 2 pts., acet. of pot. 1 pt.) causes them to swell up, without separating them from the glass, and although it makes them paler, does not change them. In some cases, it is better to take the fluid for examination from the top of a culture tube, in others, from the bottom, where are usually found the permanent spores. In the examination of fresh bodies or liquids, like urine, it is recommended to add carbolic acid or thymol to the fluid, to collect the sediment, and after the addition of a few drops of a half per cent. solution of caustic potash, to stain. A solution of osmic acid (1 : 100) serves to harden the mass of filmy bacteria found on the surface of a liquid, and surrounded by a zooglœa mass.

A strong solution of iodine (2–5 per cent.) stains them a yellowish brown; united with sulphuric acid it gives some of them a blue color. All the different aniline dyes, eosin, fuchsin, saffron, Bismarck brown, methyl-green, blue, and violet, are all well suited for staining. Methyl-blue and violet, whether used in strong or weak solutions, seem to have the strongest affinity for germs. Aniline brown is best for photography, but as it is rendered colorless by acetate of potash, the germs must be preserved in glycerine and water. While tube-casts and the granular membrane in urine are also stained blue by methyl-blue, the staining is not so deep as with the germs. Hæmatoxylin preparations, after thorough washing, can be mounted in glycerine, or a solution of chloride of calcium. Glycerine and acetic acid stains them a yellow brown. They are stained red by carmine, hydrochloric acid and glycerine, and brown by carmine, if, subsequently, they are treated with the tincture of the chloride of iron. The acid preparations of the anilines, where the coloring principle seems to lie in the acid, like the picrates, do not stain them. The anilines have the further advantage that they soften the germs without loosening them from the glass, unless too weak a solution is used. A concentrated solution of sulphate or acetate of calcium (1 : 2) can also be used to preserve them, after they have been stained by methyl-violet. In examining animal tissues it is proper to harden them in alcohol, make the sections, and stain in the usual manner. After the tissues have been stained, a weak solution of carbonate of potash will decolorize all the animal tissue, without affecting the germs.

There are four fundamental forms: * spheroid or spherobacteria, rod-shaped or microbacteria, thread-like or desmobacteria, and spiræ or spirobacteria †. The reaction with iodine and sul-

* Klebs (*l. c.*) divides the pathogenic germs into two classes: The monadina, and the microsporina. The granules of the monadina are larger, and lie imbedded in a sort of jelly, which forms a clear zone around every granule. The granules themselves are arranged in parallel rows, and the brown color of septic micrococci is lacking. They are less stained by the anilines. Septic processes, like diphtheria, are produced by the microsporina. The monadina bring on inflammatory processes, attended with the formation of connective tissue, such as the acute exanthemata, and rheumatic, nephritic, hepatic, and cardiac inflammations.

† The coccobacteria (1!) are micrococci, which are capable of transforming themselves into short rods, and form groups united by zooglœa. While, by prolonga-

phuric acid, proving the presence of cellulose, shows them to be of vegetable origin, often microscopically undistinguishable. They can be differentiated best by their mode of growth on solid substances.

As germane with the scope of the address, we present a short description of the more important supposed pathogenic germs.

The bacilli malariæ (12) "are small rods, 5–10 m. long, which, during their evolution, become converted into tortuous filaments, which divide into joints by the formation of clear spaces in the protoplasm, or, by means of separating membranes. The filaments produce spores on the surfaces exposed to the air, and spores are developed in the interior. The spores are situated in the centre, or toward the extremities of the joints, but may be found in both places at the same time." For their growth they require oxygen, a temperature of 20° C., moderate but steady humidity, and the direct action of the sun. In the body they are only found in the cold stage of the fever (by aspiration of the spleen).*

The bacillus anthracis is found in translucent filaments, more or less segmented. At the end of forty-eight hours, in culture fluids, it shows germs distributed in series along the filaments. There is a connection of gelatinous matter, which is absorbed, and eventually the germ drops off, being reduced to so called germ-dust, which can be cultivated after lying dormant for years. The bacilli (13) of putrescent blood are rounded at the ends, while the bacilli anthracis are perfectly square at the same place.

The micrococcus diphtheriæ is a minute spheroid, found particularly in the mucous and submucous vessels and the lymph channels. It is (14) 1–1½ m. long and 3 m. broad in the deeper portions, and 4 m. long and 1.1 m. broad in the superficial areas. They are generally associated in pairs, more rarely in chains, but frequently in colonies, in which the gelatinous mass can be cleared up by acetic acid. Their products seem to be fatal to themselves, as in cases of convalescent diphtheria very few can be found, but in their place, bacilli, leptothrix and the bacteria of putrefaction. The presence of rod-bacteria in diphtheritic membrane (8) is proof that it has commenced to putrefy.†

The bacillus typhi, 80 m. long and 5 m. broad, found mainly in the lymphatic organs of the abdomen (intestinal mucous membrane, intestinal glands, spleen), is more slender than the ordinary bacteria of putrefaction (16), has permanent spores (17), and takes staining less distinctly.* It is not found in the intestine, where there is even a tuberculous ulceration.†

The spirochæte Obermeieri is a non-extensible flexible filament, found in the blood of relapsing-fever patients only during the pyrexia, but is never found in the urine. On the contrary, the urine is full of micrococci during the remission. It can live (20) 14 days at 22° C., 15 hours at 38° C., and only 4 hours at 40° C.

If an albuminous or saccharine fluid is exposed to a high temperature, and the entrance of spores carefully excluded, it will remain perfectly unchanged, but if we add to it some putrefying substance, or some of the bacilli anthracis, we will find a decomposition apparently identical in both cases, except as regards the microscopic examination, and the result of the decomposition, for, in the former case the smell of putrefaction will manifest itself, while in the other only ammonia will be noticed. The innocent micrococcus (21) ordinarily found in the mouth has been transformed by cultivation into a variety of microgerm which speedily kills the animal inoculated (by septicæmia).

The ordinary hay-bacillus, (22) by cultivation in egg-albumen, and then in blood serum, has been transformed into the bacillus anthracis, but this has been strenuously denied (Koch *l. c.*), and, even if it were the case, it must be proved that the same transformation can take place in the body. Air and moisture seem better for cultivation, and an incubator, or moist hot air bath, is almost a necessity. After tubes have been sterilized, it is well to stand some aside for control-experiments, so as to be thoroughly convinced that whatever was added brought on opacity and decomposition of the culture fluid. Mechanical disturbances (23) and electricity apparently in-

tion of the cocci, rods are formed, which break up into chains by segmentation.

* In the examination for this germ, the air, taken directly over the surface of the ground, was drawn through an aeroscope of peculiar construction which allowed the deposition of all filaments and spores on a glass plate covered with gelatine and glycerine.

† It consists (15) of long, jointed, mycelial rods, and spores of two kinds; the one, oval or round, giving rise, by a gradual process of elongation, to the mycelium; the other, rectangular, and showing, after a time, minute, brilliant specks in their interior, about the size of an ordinary micrococcus.

* Wernich (*l. c.*) denies *in toto* these specific criteria of the bacilli typhi, and believes that the ordinary bacteria of the intestinal canal, by a process of ascent into the small intestines, find circumstances more suited to their propagation, and then produce typhoid fever.

† There is no doubt (18) that the bacilli typhi are present in every typhous plague of the intestines, as long as there is a process of development of the disease. They appear to reach the height of their development in fourteen days, and then undergo retrograde metamorphosis, after necrosis and ulceration or degeneration of the cells has taken place.

terfere with the growth of germs in culture tubes. The microbe of chicken cholera (24) reaching only slight development in sterilized urine, and destroyed in yeast solution, is cultivated most successfully in chicken broth, at a temperature of 25°–35° C.; and can be attenuated by allowing an interval to elapse between successive cultivations, and by cultivating at a temperature of 40°–45° C. The (25) micrococci of wounds do not produce putrefaction in culture fluid, and develop best when removed from the air. The micrococci of diphtheria, which multiply best at 40° C., and are arrested in their movements by a temperature of 70° C., do not need a large supply of oxygen, and are generally found at the bottom of a culture tube, while the bacilli are at the top. The animal organism (14) appears to be the best culture medium. The bacterium (26) killed by heating for several hours to 50° C., slowly increases even at 5° or 6° C., but, like the micrococcus prodigiosus, (27) (in quality of a blood-red color) develops best at 30°–35° C.

Blood serum is not a good medium for cultivating the bacillus septicæmiæ, which will not grow in the mucus of a healthy urethra, (Lister *l. c.*) but develops best in a hay-infusion, while the bacillus anthracis will not grow in a hay-infusion, but developes best in blood or aqueous humor. In all experiments, it is advisable to use the second or third cultivation, to prevent the admixture of other spores, and to develop the germs in the most favorable way. As nearly all bacteria contain sulphur, some little can be used in the culture fluid.

Sterilized bouillon, chicken or meat extract, ascitic fluid* aqueous humor, egg-albumen, blood serum, and hay-infusion are some of the substances used for culture fluid.

Among the artificial fluids are:—

PASTEUR'S.

	Gm.
Distilled water,	100
Sugar,	10
Tartrate of ammonia,	1
Ashes of 1 gm. of yeast,	075

(Bucholtz replaces the yeast by ½ gm. of phosphate of potash.)

COHN'S

	Gm.
Phosphate of potash,	1
Sulphate of magnesia,	1
Tribasic phosphate of lime,	01
Tartrate of ammonia,	2

Water, enough to make cc. 20.

* (Although the ascitic fluid, from a case of two years' standing, proved to be antiseptic, from the phenol and indol it contained. Salkouski *l. c.*)

KNOP'S.

	Gm.
Phosphate of potash,	1
Sulphate of magnesia,	1
Nitrate or chloride of lime,	2

Water, cc. 20.

Gelatine (28) added to culture fluids, in a proportion of 3–4 per cent., furnishes a good substance for solid cultivation, although potatoes, first boiled and then sliced, are the best medium for the dry cultivation, which appears to be the best mode of discriminating them with the naked eye. The only way of sterilizing fluids is by heat, and for this purpose, dry is better than moist heat. A temperature of 70° C. is generally sufficient to kill all bacteria, but it requires a prolonged exposure at 120° C., or even higher, to kill the spores. Very low temperatures, even as low as 40° C. (Irisch *l. c.*), fail to kill the spores.*

* Passing (29) the motes, seen in the air, through marble moistened with potash, and glass wet with sulphuric acid, and through a variety of ethers and alcohols, did not sterilize, though they were destroyed by their transmission through a flame.

(*To be continued*).

Correspondence.

Morphia Poisoning.

Ed. Med. and Surg. Reporter :—

I was called and arrived at 12.05 A.M. of 10th March, 1882, and found well developed woman, aged 22, lying on back in bed, mouth open, jaw pendulous, tongue dry, eyelids closed, pupils contracted, skin normal, respirations 5 per minute, pulse regular for 4 or 5 beats, and then fluttering and not easily counted. Was informed by her mother that she had taken "morphine" in a freak, to offset a joking statement of her husband, that he was going to come home drunk that evening; that she had taken it on an empty stomach, about 7 P.M., and had laughed over it. They supposed she had not taken enough to injure her; after a stage of excitement she had gone to bed and fallen asleep, about 11 P.M., and in half an hour had awaked her husband, who was asleep by her side, by urinating upon him, which caused him to investigate her condition. She was menstruating at the time; was said to be unused to effects of morphia. I have since had good evidence that she took six grains of sulph. morphia.

Treatment.—A large and very efficient mustard poultice was applied over stomach and allowed to vesicate, and warm irons so closely applied to feet as to unintentionally burn both severely. At 1.05 A.M., ⅓ gr. sulph. atropia was injected in arm; pulse 26 to ¼ minute. At 1.25 A.M. injected 30 minims sulph. ether; at 1.40 A.M. injected 30 minims spts. ammon. aromat. in abdominal wall; pulse weak, eyes slowly dilating and responding to light; respirations 8 per minute, in following manner: 4 resp. in first ½ minute, and 4 in remaining ¾ minute, irregularly distributed and then no effort to respire for from 1½

to 1⅝ minutes. At 2 A.M. rather better pulse and respiration. At 2.15 A.M. respiration 7 per minute, divided as before in same manner. At 2.30 A.M. had 14 respirations in 3 minutes. At 3 A.M. pupils dilated; general condition seemed worse. At 3.10 A.M. resorted to artificial respiration. At 3.25 A.M. first used battery, according to rules, to induce respiration. At 3.45 A.M. respiration 10 per minute, which in 2 minutes increased to 14 per minute; general condition improved. At 4.15 A.M. forced a cupful of strong black coffee down throat, and she progressed toward recovery. The injections of ether and arom. spt. ammonia were repeated 5 or 6 times at irregular intervals. She says the first sensation she was conscious of during effort to resuscitate was the pain in feet, caused by hot irons, and I believe the burns on bottoms of both feet a powerful factor in arousing her. The treatment was directed to meet the indications, as they appeared, and each seemed to fit and fill a place that without would have left a fatal void. The case seemed a hopeless one, from amount taken on empty stomach, the time that had intervened, and the character of the respirations. C. POLLOCK, M.D.

Muncie, Ind., April 17th, 1882.

NEWS AND MISCELLANY.

The Advancement of Scientific Medicine by Research.

At the first meeting of the executive committee of the new association, the treasurer, Dr. Wilks, announced subscriptions amounting to over £1000. Sub-committees were appointed to report—1, on the present hindrances to research, due to the working of the Vivisection Act; 2, to report on the best ways in which exact researches in medical science can be encouraged; 3, to prepare a list of papers to be reprinted and circulated for the use of the profession, and through their means for the public; 4, to arrange for asking the help of those interested in the objects of the association as corresponding members in the principal towns of the kingdom.

Sanitation Justified.

The *British Medical Journal* says: "A noteworthy instance of the effect of improved sanitation upon the rate of mortality at Carlisle is mentioned by Dr. Elliot, in his last report on the health of that town. In 1841, the census gave the population as 23,959, and during the seven years (1842-1848) the average yearly mortality was 728; whereas in 1881, thirty years later, the mortality was only 717 among an increased population of 35,866.

Fame.

There lately went the rounds of the medical press an item from a South American medical journal, to the effect that the autopsy on the late President Garfield was made by *Dr. Longbranch*. Now comes something almost as bad from London. The *Medical Press and Circular*, of April 5th, 1882, says "Our American exchanges announce the decease of a prominent and well-known representative of American Surgery, Dr. Joseph Pancoast, Professor of Anatomy in the *University of Pennsylvania* from 1841–1874." Verily fame goes but a short way. Our trans-Atlantic brethren had some idea that Professor Pancoast was a great man, but the idea must have been a very vague one.

Items.

—Herr Krupp, the famous Prussian cannon maker, who employs many thousands of men, has compelled them all to be vaccinated. He provides the virus free of charge, and the penalty for refusal is immediate dismissal.

—The Senate of the University of Sydney have initiated a medical school in connection with that institution. They propose to confer three degrees —Bachelor of Medicine, Master in Surgery, and Doctor of Medicine.

Errata.—In second formula on p. 571, for ol. myrrhæ read *ol. morrhuæ;* in fourth formula, for syr. amyg. amar., read *syr. aurant. cort. rub.*

QUERIES AND REPLIES.

Drugs.—1st. Yes, if he wishes to do so, though it is not generally considered the proper thing 2d. Yes. 3d. Yes.

T. C. W. asks our subscribers to furnish their experience with chrysophanic acid in skin diseases; what strength they have used, etc.

T. C., Pa., would like to know the name for twin cows as known in the market, especially in England.

T. & B., N. Y.—You will find formula for Infusion of Golden Seal in this journal, May 6th, 1882.

MARRIAGES.

DANA—FARLEE.—On Thursday, April 27th, at the residence of the bride's parents, No. 50 West 46th st., New York, by the Rev. James H. Hoadley, Dr. Charles L. Dana, of New York, and Lilian G., daughter of George W. Farlee.

DAVIS—LEIGH.—On Thursday, April 20th, at St. John's Church, Bridgeport, Conn., by the Rev. E. W. Maxey, D.D., John Edward Lounsbery Davis, M.D., of Nyack, N. Y., and Mary Sophie, daughter of Wm. Leigh, Esq., of Bridgeport, Conn.

GARNER—APPLEBY.—In Spotswood, New Jersey, April 27th, 1882, by Rev. Chas. M. Parkman, Henry B. Garner, M.D., and Miss Amanda V. Appleby, both of Spotswood.

HALL—PEOPLES.—On Thursday, April 27th, at the residence of the bride's father, by Rev. L. Marks, D.D., assisted by Rev. Henry Rumer, H. B. Hall, M.D., of Riverton, N. J., and Reba, daughter of Mr. John Peoples, of Wilmington, Delaware.

HARRISON—NICOLL.—On May 6th, at the residence of the bride's parents, by the Rev. F. C. Putnam, Dr. S. D. Harrison, of Jersey City, and Agnes C., daughter of Dr. John Nicoll, of New Haven, Conn.

DEATHS.

DE YOUNG.—Dr Horace De Young, a prominent physician of Mauch Chunk, died suddenly, May 10th of epilepsy.

PAINE.—In London, England, May 1st, Dr. Horatio Paine, in the 40th year of his age.

SEARY.—On the 8th of May, Charles W. Seary, M.D., in the thirty-ninth year of his age.

WOOD.—In New York, on Thursday, May 4, 1882, of pneumonia, Dr. James R. Wood.

YOUNG.—May 3d, John Henry Weir Young, M.D. in the 23d year of his age.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

ATROPIA—SOME POINTS IN ITS PHYSIOLOGY AND THERAPEUTICS.

BY T. CURTIS SMITH, M.D.,

Of Aurora, Ind.

Like the plant from which it is derived and of which it is the active principle, atropia is anodyne, antispasmodic, diuretic, antisudorific, and also a powerful cardiac and respiratory stimulant. A remedy having such a wide range of action must become valuable in its therapeutic applications. It must also, of necessity, have a wide range of physiological effects on the human system. The gross effects are noted, as fullness of the brain with blood, fullness of the peripheral surface everywhere, greater activity of the general circulation and especially that of the capillary circulation of the skin; there is mental hebetude, mydriasis, dryness of and a feeling of constriction about the fauces. When the dose is very large it produces some pain in the head, vertigo, dimness of vision from the admission of too much light through the dilated pupil, flushed face turgidity of scalp and head, difficult deglutition, wakefulness, dryness of skin, with a scarlatinal rash, increased urinary secretion; there may be also considerable delirium, and finally, convulsions and unconsciousness. The pulse becomes very rapid and forcible until the vital powers are overcome, when it grows gradually weaker. The respiration is also much increased in frequency. In many cases there is increased peristaltic action, with griping. The mucous surfaces are everywhere dry. In females poisonous doses are apt to produce a catamenial flow, more or less free.

From these gross effects of atropia we propose to turn to view some of its influences over secretion, the circulation and respiration, and through these look a little to its therapeutic applications.

This agent produces its effects either through stimulating the sympathetic system of nerves or by more or less complete paralysis of the organic system of nerves. In the matter of the secretion of saliva. Nothing is better known, perhaps, than the fact that atropia checks its flow; stops it entirely in full doses. How does it do this? By producing paralysis of the chorda tympani nerve, which belongs to the organic system, and which regulates the secretion of the submaxillary gland. It is, in some sense, a compound nerve, having two sets of fibres, one of which acts upon the gland cells, causing them to secrete saliva. The other set of fibres induces dilatation of the arteries of the gland, and thus supplies blood more abundantly, from which saliva may be drawn by the cells. The failure of this secretion under the power of atropia is not due to the vaso-inhibitory fibres of the nerve. It is due solely to paralysis of the secretory fibres. This was shown to be so by Heidenheim, who found that when the chorda tympani was irritated after the use of atropia no saliva is secreted by the submaxillary gland, but its vessels become dilated as usual. This experiment showed clearly the existence of two sets of nerve fibres in the chorda tympani nerve; one set controlling the blood supply, the other, cell action. It was found also that irritation of the sympathetic caused a return of the secretion after the use of atropia. The

termination of the sympathetic filaments "must therefore have a different relation to the secreting cells from those of the chorda tympani." It is through its influence over these nerves that the secretion of saliva is controlled by atropia. The increased flow of urine under the use of atropia is largely due to increased blood pressure on the glomeruli of the kidneys, but partly owing to an increased flow of blood through the organs. It will be noted further on that the action of the heart is accelerated and its force of contraction increased. This would naturally increase the quantity of blood driven through any of the internal organs in a given time, and therefore, among others, increase that to the kidneys. This would give opportunity for the glomeruli to extract an increased quantity of urine from the increased flow of blood through them. But no doubt no considerable difference in the quantity of urine discharged under the use of atropia is due to the diminished power of perspiration. The complemental play of discharges between the skin and urinary organs is well known to all physiologists. The increased diuresis under atropia, then, may be accounted for (*a*) by increased blood pressure, (*b*) by increased flow of blood through the kidneys, and (*c*) by the diminished perspiration.

Here we see the influence of atropia over the organic and inorganic systems of nerves as plainly as in that over the salivary secretion. We sometimes meet with cases of impending death from uræmic poisoning, where the blood-pressure is very low, the heart action feeble, and capillary circulation sluggish. In such cases a full dose of atropia hypodermically is worthy of a trial, for effects on the kidneys, provided there is not a weak heart that forbids it, because of the increased strain it would bring upon its walls. Atropia has a most marked influence over the circulation of the blood. This influence is exerted by the power this agent exerts over the nerve centres primarily, and through them, over the heart and vessels. The manifestations of the effects of atropia over the capillaries through the vaso-motor system of nerves is apparent to every one who has ever taken or administered full doses of it, in health or disease.

Its influence over cardiac movements is effected through the pneumogastric as its inhibitor, on the one hand, and the accelloratores, on the other. The balance of power between these nerves in their influence over cardiac action, in good health, is equal. The pneumogastric arises close behind the olivary bodies in the medulla, and, after its exit from the skull, descends the neck to the inhibitory ganglia of the heart. It is the nerve that inhibits the heart's action, slows or checks its movements. Physiologists have clearly demonstrated this fact by experimentation. They have uniformly observed that irritation of the pneumogastric at its centres, in its course, or in its final peripheral terminations, produces a diminished number of cardiac contractions. We sometimes meet with cases where persons have been greatly shocked by a light blow on the stomach, or over the solar plexus. Sometimes the pulse is rendered very slow by such blow, or it may be stopped altogether, death resulting instantly. The reason is apparent. The impression is carried up to the nerve centre of the pneumogastric in the medulla, via the sensory nerves and spinal cord. The nerve centre in the medulla transmits a strong impression along the nerve, or the nerve is strongly stimulated. It, therefore, acts with more than its normal power. Being an inhibitory of the heart, this stimulus, therefore, causes it to more or less suddenly slow or entirely check the heart's action.

Blows and injuries to the abdomen are not alone in their reflex influence over the pneumogastrics. Any injury anywhere produces, through reflex action, a similar but not so powerful an effect. Hence it is that sharp stings or severe pain influence cardiac action. And we find the contractions increased in number and force, or slowed, according to the impression conveyed through the reflex sensations carried to the cardiac nerves.

It is well known that if the pneumogastric nerve is divided in the neck, the heart runs rapidly; and that if the divided nerve be irritated, the action of the heart is slowed very much. This shows that the power to inhibit cardiac action is seated in the medulla, and that the vagi are the nerves through which that power is transmitted to that organ to regulate its action. One of the functions of this great nerve, then, is to slow the heart, keep it in bounds as to its rapidity of action. It is, in some measure, to the heart like the governor to the steam engine. Any remedy, therefore, that stimulates, or gives increased tone to it, will slow the action of the heart. Among these agents we have, foremost of all, digitalis, which gives strength to the heart, while veratria, muscarin, etc., may slow the heart without giving increased strength; in fact, may weaken its power of contraction.

But we have also nerves that increase the rapidity of the heart's action, and stand opposed to the sway of the pneumogastric—the accelloratores. These also arise in the medulla, and

passing down the spinal cord with the vertebral artery, emerging "through the last cervical and first thoracic ganglion, and passing to the heart, probably end in the excito-motory ganglia. Some accelerator fibres sometimes pass through the cervical sympathetic of the heart. They are the antagonizing nerves of the vagi, but unlike the vagi, are not constantly in action." (Arch. Dixon, Henderson, Ky.)

The cardiac function of the vagi is to regulate or slow the heart, while the accelerators increase its rapidity of motion. Over these nerves atropia exerts a marked influence. Perhaps it were better to say this agent exerts marked power over that portion of brain and spinal cord that give origin to these nerves, and those sympathetic ganglia that have in some measure control over the heart, and also control over the contractility of the blood vessels, great and small, especially the latter.

It has been clearly set forth and demonstrated that the nerves controlling the calibre of the vessels are compound in their character. These are the vaso-dilators and the vaso-constrictors. These are made to act under stimulus, so as to either dilate or constrict the vessels, especially the capillaries, according to the character of stimulus applied, and the manner of its use. It it now well known that we have many remedies that produce these effects. For instance, ergot effects contraction of the capillaries. Its therapeutic uses are thus often plainly indicated. Others produce dilatation and are used accordingly. Few remedies exert more power over the vaso-motor system of nerves than does atropia. This effect renders its therapeutic uses of very great importance. Hence, the need of their study and comprehension for daily use. We know of no clearer setting forth of the course and functions of these nerves than that given by the writer above named. (*Indiana Medical Reporter*, January, 1880.) "The vaso-constrictor and vaso-dilator nerves emerge from the spinal cord through the spinal nerves; the constrictors being limited to the vaso-motor centre in the brain. This centre, according to Ludwig, is situated between the calamus scriptorius and the corpora quadrigemina, and from it fibres arise and pass down the spinal cord, emerging as follows: For the head, instead of passing directly, they go through the cervical sympathetic to the blood vessels of the ear, face and pia mater; for the upper extremities, through the sympathetic and brachial plexus; for the lower extremities, through the lowest spinal nerves and sacral plexus, and in the trunks of the anterior roots of the lowest lumbar and sacral nerves to the sympathetic, and thence to the lower extremities; for the cavities of the nose and mouth, through the trigeminus; for the abdominal contents, through the splanchnics, which are the most important of the vaso-motor nerves." It will be seen that every part of the system is connected with both the organic and inorganic systems of nerves. The constrictor ganglia that hold the calibre of the capillaries under control are everywhere present and ready to exert their power. Indeed, the exertion of this power is constant, and any failure of it permits dilatation of the capillaries and lowered blood pressure.

There is one other nerve to which we wish especially to refer at this time, the "depressor" nerve of Cyon and Ludwig, named for its discoverers. Its power is far reaching. It has influence over the whole vaso-motor system. It arises from the pneumogastric by one root, and from the superior laryngeal by the other root, and sends its fibres largely or altogether to the heart, in which they terminate, but the manner of their minute distribution is not yet fully known. When irritated it "inhibits the vaso-motor mechanism supplied by it," (*loc. cit.*), and "paralyzes the main vaso-motor centre in the brain, and thus causes the whole capillary system to dilate" (*loc. cit.*). When it is divided and then irritated the capillaries everywhere dilate, especially those of the abdominal organs. Of course blood pressure is at once reduced by diminished resistance to its passage through the capillaries. It will be seen that the superior laryngeal nerve is a branch of the pneumogastric, the first one given off in the neck. It "is the nerve of sensation to the larynx" (Gray), and arises from the middle of the inferior ganglion of the pneumogastric. This "depressor" nerve of Cyon and Ludwig is, then, essentially derived from the pneumogastric. Its great power over the vaso-motor system of nerves must be referred back to the seat of the origin of these special fibres in the brain, the nerve itself being only the medium through which such power is transmitted to the parts and nerve centres influenced by it. Any agent that would stimulate this nerve, or the seat of its origin, would inhibit the vaso-motor tract, over which it exerts a powerful influence. From what has been before stated of the power of this nerve, the agent would also paralyze the whole vaso-motor centre in the brain, and thereby permit or produce dilatation of the capillaries in general. Does atropia have any special power over this nerve? If atropia should paralyze this nerve, there would be general dilatation of the

capillaries. It seems to me that atropia does not exert such action, for it stimulates in a marked degree the vaso-motor centres of the brain, and produces contraction of the capillary system of vessels.

The action of this nerve, however, over the circulation of the blood may, at times, of necessity, be exceedingly salutary. We have said that the pneumogastrics may be looked upon as the governors of the heart's action, in some measure like that of the governor of a steam engine. On the other hand, the "depressor" nerve of Cyon and Ludwig may be looked upon, as Foster has said, in the light of the safety-valve" of the engine. "When the heart is surcharged with blood, the impression is carried by the depressor nerve to the vaso-motor centre" (*loc. cit.*). This it paralyzes, and allows the capillaries to dilate and receive the excess of blood. In this way the overstrained heart is relieved of its surplus of blood, cardiac dilatation or rupture is prevented, and when the cause of the disturbance is removed, the balance of power is restored and the circulation runs normally and smoothly again. Indirectly, then, this nerve has much to do with the influence exerted by atropia and other vaso-motor stimulants.

Atropia is a powerful cardiac and respiratory stimulant. It stimulates the accelerators, the function of which is to increase the action of the heart. But it also paralyzes the vagi, and thus the cardiac contractions are rapidly increased. The blood pressure is at the same time raised, because atropia stimulates the vaso motor centre in the brain, which the nerve transmits to the peripheral ganglia, thus securing contraction of the capillaries through their constrictor fibres. When there is thus a general contraction of the capillaries with increased cardiac action, the rise in the blood pressure necessarily results. This agent also paralyzes the splanchnic nerves. This would permit dilatation of the capillaries it supplies, but for the fact that the constrictor fibres are supplied with stimulus or are stimulated to action by the vaso-motor centre of the brain, and thus the blood pressure is kept up.

It will be seen that large doses of atropia would be liable, through the mode of action above pointed out, to throw an overplus of blood upon the already stimulated and rapidly contracting heart. If this overplus be permitted to continue its accumulation in quantity and pressure of blood on the heart, that organ must either dilate its cavities to receive the excess as it rushes into it or its fibres must give way. Cardiac rupture and death would be the immediate result.

Here we see the value and beauty of the part played by the "depressor" nerve above referred to, for when this centralization of blood pressure is felt at the heart, an impulse is sent up this nerve to the vaso-motor centre in the brain, and by producing paralysis of that centre the stimulus of the vaso-motor constrictors is lost, and there results dilatation of the capillaries, especially of those under the control of the splanchnic nerves. This dilatation permits a large retention of blood in the capillaries, and thus the overplus of blood at the heart with its excessive pressure is removed and death prevented. The great importance of this depressor nerve and its action as a safety valve is thus clearly brought out. Dr. Dixon (*loc. cit.*) tersely sets forth its action thus: "If the heart be surcharged with blood an *afferent* impulse is sent up the depressor nerve to the vaso-motor centre and an *efferent* impulse is sent down from it through the constrictor fibres of the splanchnic, paralyzing them, and dilatation at once takes place." Safety is thus brought where death was imminent. In this instance we see, as in many others, the conservative and self-protecting powers of the human organism.

That atropia is a powerful cardiac and respiratory stimulant has already been stated and is well known. Great use may be made of this important fact in its therapeutic application. In the administration of anæsthetics great trepidation is felt on the part of the giver and receiver of the agent, for no one can tell whether the patient may come out of its power in safety, or be landed in eternity while yet unconscious. It has been the habit of the writer, for years, to give a hypodermic injection of atropia—$\frac{1}{90}$ to $\frac{1}{60}$ grain—before using anæsthetics. He has not only had no cause to regret this practice, but has been highly pleased with it. Von Graefe recommends the same practice. It in no way interferes with the anæsthetic, but it does help to maintain the cardiac and respiratory functions while anæsthesia is present, and for some time after it passes off. I have often noticed in cases where great shock is present, and where it is desirable to anæsthetize the patient in order to operate, that a pretty full dose of atropia hypodermically given ten minutes before using the anæsthetic will bring up the fullness and force of the pulse, deepen and regulate the respiration; and this effect is not lost when the anæsthetic is brought to bear in its needed power to prevent suffering during the operation.

As a remedy in severe shock, where there is feeble circulation, cold extremities, pale surface,

and sighing or difficult respiration, we know of no agent equal in power and of as great value as atropia sulph. used hypodermically. The same may be said in reference to the collapse resulting from cholera, cholera morbus, or sudden loss of blood. I have seen cholera patients that had been given up to die rally in half an hour under the hypodermic use of $\frac{1}{30}$ grain of sulph. atropia, so as to be pronounced out of danger by those who had considered them as good as dead before its use. I know this is strong language, but I also mean all I say. These happy results are brought about by the power this agent has as a cardiac and respiratory stimulant and through its influence over the capillaries, through the vaso-motor system of nerves.

In some cases of sunstroke, where there is a marked tendency to apoplexy, and where the pulse is somewhat hard, but irregular, and the respiration is labored, and where there may be great doubt as to whether we should stimulate or use depressing agents, we may well remember that a severe shock has been rendered to the system, under which it is laboring, and that gentle stimulation of the nerve centres is perhaps the safer course. Then, if we remember the marked effects atropia has over the vaso-motor nerve centres, and its tendency to distribute the blood equally in all parts of the system, I think we will find in its careful use a most valuable and safe remedy. This effect may be had by repeated small doses of atropia, hypodermically given, until its effects begin to be apparent. In this class of cases alcohol is unsafe; venesection is dangerous, especially in drinkers. Atropia is, at least, safe, when discreetly managed.

Advantage may be taken of these effects of atropia in some cases of sunstroke. It is, however, not a remedy to be injudiciously used, or used without clear discrimination in these cases. Where there is a strong apoplectic tendency, shown by turgescence of the head, and a hard, full pulse, and heavy, deep respirations, this is not the remedy needed. But in many cases of sunstroke there is present an irritable stomach, nausea, vomiting, cool extremities, small, weak pulse, difficult respiration. In these cases the pathological condition is that of prostration, and the tendency to death is by asthenia, or swift failure of life from prostration. The nerve centres are overcome and death is imminent. In these cases it is the common practice to give alcoholic stimulants—generally a very good treatment, and one that has averted impending death in thousands of cases. But it has no doubt been the experience of many, that in some of these cases it is quite impossible to obtain the stimulant effects of alcoholics in any form, on account of the irritable condition of the stomach. No remedy is retained, and life ebbs away, while we stand powerless to secure the needed stimulant effects of any agent by way of the stomach.

In such cases, atropia given hypodermically has acted most kindly and beneficially. The irritability of the gastric organ does not prevent its administration or its stimulant effects. In a few minutes its stimulant power is made manifest by rendering the pulse fuller and steadier, and the respiration deeper and easier; the capillary circulation is restored to its normal balance, cerebration becomes healthy, and the danger point is so easily past as to be rendered less appreciable than would have been the case under the use of stimulants by the more common manner of administration.

These effects of atropia over the circulation and respiration are what render atropia so valuable in cases of poisoning by opium and its salts, and by muscarin, physostigma, aconite, etc. These have more or less direct tendency to depress the actions of the heart and lungs. Fothergill, at one dose, gave a grain of atropia sulph. to antagonize a lethal dose of opium, in tincture. This is giving a lethal dose of one deadly poison to destroy the effects of a lethal dose of another poison. This was an extreme case, and demanded extreme measures. The result justified the treatment. This case, however, should not stand out as one governing practice in every case of narcotism by opium, for the extreme dose of one grain of sulph. atropia is very deadly and dangerous. But a proper balance may be found in the use of these agents, so that one may antagonize the other, when the poisonous effects of either is observed. I believe Bartholow places the ratio of antagonism at atropia gr. j to morphia grs. xvj. It makes a good formula for hypodermic use.

Professor Frazer found atropia very efficient in restoring the failing circulation and respiration under the poisonous effects of calabar bean. Mr. H. A. Hobbs (*Compendium Medical Science*, July, 1872, p. 46) reports a case of severe poisoning by the ingestion of belladonna liniment. The manifestations of poisoning by this agent were extreme. He used calabar bean to counteract the effects of the belladonna. The effects were prompt and markedly favorable, and recovery occurred quite perfectly in a reasonably short time.

The common uses of atropia in diseases of the eye, and for neuralgia, and asthma, for its influ-

ence over peristaltic action of the digestive tube, and for its power over muscular fibre in general, we have not space now to enter upon. Furthermore, much of this would be needless, as all the profession are, no doubt, well informed as to these common uses of atropia.

A summary of what we have endeavored to set forth as the effects of atropia may be expressed thus:—

(*a*) It is easily administered; (*b*) is not an irritant to the stomach or tissues; (*c*) is a most powerful cerebral stimulant; (*d*) has special influence over the vaso-motor nerve centres; (*e*) is a powerful cardiac and respiratory stimulant; (*f*) and through these effects on the organic and inorganic system of nerves, is a most valuable agent in the profound depression resulting from many forms of disease, and from the shocks of injury and operations; and also, (*g*) available to prevent the serious results of anæsthesia; and (*h*) is one of the safest and best stimulants in some conditions resulting from sunstroke.

No agent in general use requires greater care and discrimination in its use, and no one will yield more happy results in well chosen cases. But it is capable of deadly mischief, as well as of great good.

THE FATALITY OF ETHERIZATION IN CHRONIC KIDNEY DISEASE.

BY JOHN B. ROBERTS, M.D.,

Lecturer on Anatomy and on Operative Surgery in the Philadelphia School of Anatomy.

In the MEDICAL AND SURGICAL REPORTER of April 29th, 1882, there appears the following sentence:—

"Concerning the administration of anæsthetics, especially ether, to patients suffering with any form of chronic kidney disease, there seems to be but one opinion, as expressed by all authorities, *i. e.*, that such procedure is, *as a rule, followed by fatal results*; and the weight of testimony confirms this assertion."

This assertion is so at variance with my own opinion, and with my understanding of the views of surgical authorities, that I desire to criticise it, although it was written by a personal friend.

In discussing the statement, I shall endeavor to prove, first, that such an opinion is *not* "expressed by all authorities;" second, that such procedure is *not*, "as a rule, followed by fatal results;" third, that the danger is *not* the same in "any form of chronic kidney disease;" and therefore, finally, that the weight of testimony does *not* "confirm this assertion."

Agnew says*, "Ether may be given with impunity to persons suffering with renal disease." Dr. Henry M. Lyman, of Chicago, the author of a well known monograph on anæsthetics, states, in a more recent publication*, that all diseases which diminish the energy of the heart and of the lungs tend to increase the dangers of anæsthesia, and that various nervous affections augment the risk. He does not, as far as I have found, refer at all to renal conditions affecting the result of etherization. Of course, the frequent association of heart and kidney affections might be raised as a reason for his omitting the latter; but if etherization in connection with chronic renal disease is followed, *as a rule*, by fatal results, such omission is censurable. I regret that I am unable at present to refer to his monograph on Anæsthesia, but the reference given is to a later publication, though possibly it may have been written earlier.

Gross's opinion, published, however, in 1872, is as follows:—"Certain diseases are usually regarded as contra-indicating the employment of anæsthetics .... but I have myself never allowed any affection whatever to stand in my way."† At this time Gross employed chloroform almost to the exclusion of ether.

Speaking of visceral diseases, Ashhurst asserts that anæsthesia is probably less dangerous in such cases than the performance of important operations without it; hence he does not think its use improper. ‡

Erichsen§ in speaking of chloroform, which he seems to prefer to ether, gives as a general rule, that whenever constitutional disease has not advanced so far as to contra-indicate operation, chloroform may be given. He also, however, calls attention to the fact that the most dangerous condition in which to administer chloroform is that in which, from renal disease, the blood is loaded with urea.

Under the discussion of cases in which chloroform is inapplicable, and should be given with hesitation and care, Druitt‖ speaks of brain, heart, and lung disease, but makes no mention of renal affections. His consideration of other anæsthesia is very short and does not refer to these matters. Bryant gives similar advice.¶ Holmes** only

** Principles and Practice of Surgery. London. 1875. p. 873.

discusses heart affections, and believes it safer to operate with than without anæsthesia. The article on anæsthetics, by Lister, in Holmes's System of Surgery, was written too long ago to be adduced by me as evidence, but in the additions made by Dr. J. C. Reeve, in the American Edition, issued this year (1882) I find the statement * that the urine should be examined before etherization, whenever practicable, because in diseased conditions the eliminative power of the kidneys is embarrassed, and "under these circumstances the most unfavorable results are likely to follow the administration of ether."

Turnbull does not mention † renal diseases in the section on "Cases in which ether should not be employed as an anæsthetic" (p. 27); but it is probable that reference will be made to this matter in subsequent editions, for I know he regards kidney troubles as important in this connection.‡

It will thus be seen that Reeve is the only surgical authority who speaks forcibly of the *positive* character of the danger of death from ether inhalation in kidney disease. He is, I admit, a very high authority, but he does not assert that the danger is so great as to warrant denial of anæsthesia in capital surgery. In fact, he does not raise the question. It appears, from the context, as if his words were made very emphatic rather because he desired to enforce caution, than because he feared that actual death would occur.

Emmet § lays stress on the danger of etherization in such instances, but does not discuss the subject freely, nor give advice as to the course to be pursued in *protracted* operations. I have not taken the time to hunt up and translate extracts from the German, French, or Italian authorities, because I feel sure that the opinions cited correspond with those of the majority of continental writers. My own opinion is that organic renal disease is a very undesirable complication of anæsthesia, and I have elsewhere said ‖ that "lungs, heart, and urine should always be examined before the administration, for, though lesions here should not preclude anæsthesia when necessary, the knowledge of such lesions would enforce caution and care."

This is very different from the statement that anæsthesia in cases of chronic kidney disease "is, as a rule, followed by fatal results."

Ether is often administered carelessly and without proper preliminary examination of the patient, and some practitioners are perhaps unaware of the propriety of a urinary investigation. Still, it is doubtful whether such would be convinced of this propriety or necessity by an unqualified assertion that carried with it the impression of being the result of a not impartial judgment.

2. I next shall try to prove my position that such procedure is *not*, as a rule, followed by fatal results.

Turnbull refers * to statistics which estimate that in Philadelphia there were, up to 1878, 34,980 ether administrations, with no recorded primary death and only one recorded secondary death. Lyman quotes the statistics of Andrews, giving 92,815 inhalations, with but four deaths.†

Chronic disease of the kidney is an exceedingly common affection, especially among those subjected to privation and exposure, and those addicted to alcoholic stimulation. These two classes are particularly liable to injury and disease requiring surgical attention under anæsthesia. It is impossible to believe that in nearly one hundred thousand instances of etherization (even admitting that some were repeated inhalations by the same person), there were only enough patients afflicted by chronic kidney disease to furnish four deaths, if it is true that etherization in such cases is, as a rule, followed by death. Even if we admit that the deaths suppressed or unreported would be sufficient to increase the number given tenfold, it is still impossible that there could be so little renal disease as to cause so few deaths.

It is evident, therefore, that fatal results do *not*, as a rule, follow etherization of patients suffering with renal disorders. It is scarcely necessary to state that nearly every surgeon of large experience has had or seen patients known to have chronic nephritis, who have been etherized with impunity.

3. Those forms of chronic kidney disease which interfere most with elimination would undoubtedly be the most dangerous complications of ether anæsthesia; hence it is not logical to state that patients suffering with *any* form of chronic kidney disease are liable to show fatal symptoms.

4. Enough has been said, I think, to prove to

† International Encyclopædia of Surgery, Vol. I, p. 422.

the reader that the weight of testimony does *not* confirm the assertion that "such procedure is, as a rule, followed by fatal results;" but that, on the contrary, the testimony of evidence and authority is to the effect that fatal results rarely follow the administration of ether to patients with chronic kidney disease.

That renal affections *increase* the risk of anæsthesia, I have no doubt, and I feel that anæsthesia is invariably a stage of some danger, and should be looked upon in that light by all administrators. The withholding of ether inhalation however, from patients with renal trouble, when painful operations are necessary or desirable, would be, in my opinion, unjustifiable; because the risk is comparatively slight. The surgeon should always be cognizant of the existence of such a complication; but it need not deter him from etherization, though it should make him exceedingly cautious and watchful.

The sweeping statement of the writer criticised is liable to be used unjustly against professional men, in cases where death occurs under ether so administered. It should, therefore, be refuted, because it has the weight of authority against it, and is not, in my opinion, justified by examination of the evidence.

One year ago I collected* eighteen cases of ether death reported between 1873 and 1880, and since that time there have come to my knowledge three or four additional instances. In a number of these the autopsy showed kidney changes, and such alterations would probably have been found in others if looked for. Therefore, though I might be willing to admit that in ether death renal disease is, as a rule, found, I cannot allow to pass unchallenged the statement that the administration of ether, in patients suffering with any form of kidney disease, "is, as a rule, followed by fatal results."

ANEURISM OF AORTA.

BY DR. BEAN.

Read before the Philadelphia Laryngological Society.

GENTLEMEN:—In November of 1880 I presented before the members of this Society a specimen of a concealed aneurism of the arch of the aorta pressing upon the left recurrent laryngeal nerve and producing paralysis of the left vocal band in abduction, together with a history of the case and notes of the *post-mortem*. I now have, in connection with Dr. Cohen, a somewhat similar case to present, but am more fortunate in being able to report a more favorable result.

Jacob S., a German, aged 70, by trade a carpet weaver, applied to Dr. Cohen on the 17th of May last, and in his absence was examined by me, for a hoarseness which had lasted since the preceding September, and for which he had been unable to find any relief. He gave the following history: On the 17th of September, 1879, after lifting very heavy rolls of carpet, felt, as he termed it, "a peculiar heavy stroke of the heart and a sense of extreme weakness, so that he came near fainting;" but as this soon passed off he paid no further attention to it.

On the 25th of September, one week later, he felt two strokes similar to the first. Soon after, how soon he does not remember, his voice began to grow hoarse, and gradually grew worse until I saw him, when there was slight dysphonia and voice a falsetto; this latter being due, according to Mackenzie, to the unequal vibrations of the vocal cords, and the abnormal way in which they approximate. For several months, even during the warm weather, he had suffered very much with cold feet; with this one exception his general condition was good; at no time had there been any cough or pain in the throat; no difficulty in swallowing: and up to the time of the impairment of his voice he had been comparatively well.

Laryngoscopic examination revealed paralysis of the left vocal band in adduction; the other appearances of the larynx were normal.

On a physical examination of his chest I found inspiration shrill at junction of the second sterno-costal intercostal articulation, as though from the pressure of some intra-thoracic tumor upon the primitive bronchus. Marked dullness over the same region. Could detect a blowing sound about one-half to three-quarters of an inch to the left of the sternum in the second intercostal space, synchronous with the ventricular systole. No thrills could be detected in the infra-clavicular regions. There was no difference in the size of the pupils of the two eyes. The pulse was seventy per minute and feeble; the left radial pulse was scarcely perceptible and about one-fourth of a beat slower than the right. This was also the case with the left brachial artery.

He was examined very carefully the following day, by both Dr. Cohen and myself. Examination of his urine revealed the presence of sugar in considerable quantity; this, Dr. Cohen suggested, was due to reflex irritation on the floor of the fourth ventricle, from the intra-thoracic pressure upon the branches of the pneumogastric nerve. The diagnosis was aneurism of the arch

of the aorta producing paralysis of the left recurrent laryngeal nerve; and the following treatment prescribed: absolute rest in the recumbent position; diet restricted to six ounces of solid and the same amount of liquid food in the twenty-four hours, the latter consisting principally of wine, and iodide of potassium in increasing doses, to ninety grains per diem.

On May 20th, two days after treatment was begun, the pulse was sixty per minute and feeble, while the left radial pulse could not be felt every beat.

On May 22d the left radial pulse was very perceptible, and his feet felt warm and comfortable.

This plan of treatment was followed until the first of July, when, at his earnest solicitation, he was allowed to sit up in an easy chair. At this time the blowing sound in the left second intercostal space could scarcely be detected and the left radial pulse was very distinct. Not doing so well out of as he did in bed, I tried to persuade him to return to the old treatment; this he refused to do, since which time he has been without medical attendance. An examination of his larynx at this time failed to show any change from the condition of the first visit, though the voice had improved in quality and power. An examination made on the 27th of January, 1882, more than six months after treatment ceased, showed no change in the appearance of his larynx; the left radial pulse scarcely perceptible; inspiration shrill in the left second intercostal space, though no blowing sound could be detected. In opposition to my advice he has resumed his work, which requires at times considerable effort, such as lifting heavy rolls of carpet weighing from 140 to 175 pounds each. Although at the time I last saw him, his voice was weak and a falsetto, he assured me that at times it was as good as it ever was. The presumption in the case is that the nerve is adherent to the anterior surface of the artery and still subject to the compression.

Saturnine Neuralgia.

Contrary to the opinion expressed by *Tanquerel des Planches*, that neuralgia, in the true sense of the word, is never met with in cases of lead poisoning, *Dreyfuss* (*Des névralgies saturnines, Par F. Dreyfuss, La France Méd.*) gives a description of two such cases. In the one the neuralgia affected the ulnar nerve, in the other the sciatic nerve. In both the neuralgia existed symmetrically on both sides, as has been observed lately to happen also frequently in persons suffering from diabetes. In the two cases reported by Dreyfuss the urine contained no sugar.

Hospital Reports.

HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

CLINIC OF WILLIAM PEPPER, M.D.,

Professor of Clinical Medicine in the University of Pennsylvania.

Reported by William H. Morrison, M.D.

THE GALL-BLADDER FILLED WITH GALL-STONES, WITHOUT CAUSING MARKED SYMPTOMS—ASCITES, TAPPING WITH A CAPILLARY CANULA—ACUTE RHEUMATISM, ACUTE ENDO-PERICARDITIS.

Gentlemen:—The specimens which are now before you were taken from a patient who died a short time ago. He was fifty years of age. He evidently came from a family with poor vitality. Both parents died in early middle life. His mother died from galloping consumption. He was himself married and the father of sixteen children, of whom twelve are dead and four are living, apparently healthy. A number of the children died from consumption. The whole family history is full of evidences of inherited tendencies and proofs of defective vitality.

When we examine his personal history, we find that he had suffered from the ordinary specific fevers of childhood. He had, in addition, always been subject to flatulent dyspepsia, but he did not speak of any attacks of acute pain, nor of any symptoms of habitual biliousness or derangement of the liver. He was much exposed in 1864, while in the army. At that time he caught a cold, and since then he has had a hacking cough. During the past six months the cough was worse, and was accompanied by expectoration and pain in the chest. For the last few months he rapidly ran down in flesh and strength, had fever, night sweats, and the physical signs of advancing softening in the lungs, with the formation of cavities, going through all the stages of a rapidly progressive phthisis, from which he died.

The post-mortem examination revealed a large cavity at the apex of the left lung, another at the base of the right lung, and a third about the middle of the left lung. Smaller cavities were found scattered throughout both lungs. There were extensive pleural adhesions, particularly on the right side. The base of the right lung was partially crepitant. We have, here, the history and ordinary symptoms of progressive, destructive, phthisis. I did not bring the lungs before you, as they exhibit, merely in the extreme, the ordinary lesions of this disease.

I have here the liver, for the lesions which it presents awaken questions of great practical interest. This organ is a little under the normal size. It is thicker than natural, and a little wider. It is distinctly paler than normal and both the naked eye and microscopical examinations show fatty degeneration. The capsule is not adherent nor thickened. It strips off readily, showing that there is little or no cirrhosis, although he at one time drank a good deal of liquor.

You will often find fatty degeneration of the liver in phthisis. It is not the only organ that is apt to undergo this change. It also occurs in the kidneys and heart, but the liver is particularly

prone to fatty degeneration. The reasons which may be assigned for this are various. Fatty degeneration is an evidence of defective oxidation. Whatever interferes with the full supply of blood or the carrying of the normal amount of oxygen favors the change in which the more complicated nitrogenous elements, which go to make up the cells, are replaced by the lower grade of hydrocarbonaceous elements which we find in fatty degeneration. The fact that there is in phthisis an habitual interference with the oxidation of the blood, is a distinct cause of fatty degeneration.

Secondly. Patients with phthisis very frequently use large quantities of fats and alcohols, and we know that this leads to the deposition of large amounts of fat in the tissues. When this fact is taken in connection with the depressed state of nutrition, and the inability to maintain the normal type of the tissues throughout the body, you will not wonder that in phthisis we have a tendency to the deposition of fat in place of the normal elements of the tissues. This is most marked in the liver, because it is to this organ that the hydrocarbonaceous matters pass first, from the digestive canal.

There is another abnormal condition about this liver, and one which we were not led to suspect. When I feel the gall bladder, it seems to be full of gall stones. Probably even at a distance you will recognize that the gall bladder has a pearly appearance. In health, the gall bladder presents thin walls, and the bile showing through gives them a dark color. Here, however, the peritoneal covering is evidently thickened. The main bile ducts are patulous, as I can by pressing on the fundus, force out a quantity of healthy looking bile. At the mouth of the common duct I find a large gall stone, and it is past this stone that the bile escapes. I shall now open the gall bladder, so that we can see its interior. I find a large number of gall stones. (There were fifty-one, varying in size from about twelve grains to one grain.) The largest is the one at the opening of the common bile duct. It does not lie directly in the line of the duct, but in a little pouch to one side. Let us first examine the lining of the gall bladder. It is distinctly thickened, but does not show any evidences of ulceration. It is, perhaps, a little roughened, but this has not gone on to ulceration, and the formation of pus. The bile is a little more glutinous than normal, due to some increase in the mucous secretion from the lining membrane.

Now what has caused these gall stones, and why did this man pass so many years without experiencing the least trouble, while others with, perhaps, but one or two little stones, have their lives rendered miserable, suffer attack after attack of pain and not rarely lose their lives in the attempt to get rid of the obstruction?

The frequency of gall stones is connected with at least two different conditions. One of these is the condition of the bile passages. An inflammation in the bile ducts, or in the gall bladder, or in the common duct, causes swelling of the mucous membrane, and retards the flow of bile. The inflammation of the mucous membrane forms a large amount of thick, gluey mucus, and this mixes with the bile, which gradually becomes inspissated, and little nuclei form, around which deposits occur in concentric layers, and gall stones are formed. This sometimes takes place in the gall ducts in the body of the liver. I have counted as many as a hundred and fifty in the branches of the gall duct.

The second condition is alteration in the bile itself. In consequence of some constitutional condition and disturbance of the function of the liver, the bile is thick, and viscid, and rich in the inorganic coloring matter, which for the most part forms the nuclei of these calculi. A little granule of coloring matter serves as the nucleus, around which fresh layers are deposited. I shall now make a section of one of these gall stones and pass it to you, in order that you may see how they are formed. You will observe the nucleus, consisting of a little stellate body of pigment, almost jet black in color; around this there is a paler layer, formed of cholestrin, and then there are subsequent layers of pigment. The formation of gall stones in the present case has been the result of this latter condition. We have them occurring in a gall bladder comparatively healthy.

We therefore see that gall stones may result from some morbid state of the biliary passages, or from an abnormal condition of the bile which leads to the formation of calculi while the passages remain almost normal. Once formed it is a matter of circumstance how many there are, what shape they assume and to what size they attain. I have counted as many as one hundred and fifty, and I have seen the gall bladder contain a single stone as large as an egg. When there are many they acquire a peculiar shape. They become polyhedral with a number of surfaces rubbed smooth by friction. Sometimes the gall bladder will feel as if it contained but a single mass, but on opening it a large number of stones may be found packed so closely together as to leave no room for the bile.

I mention the faceted condition, as it has an important bearing on the prognosis. I shall first describe the manner in which you look for gall stones. Mix the fæces with a large quantity of water and thoroughly stir with a stick. Then place a sieve over another vessel and pour the fecal matter on it, stirring it constantly and washing it through with more water. If a gall stone has been passed you will find it remaining on the sieve. If it is a rounded body we may hope that it was the only one in the gall bladder, and you may make a favorable prognosis as regards future attacks. If, however, you find one or more having these little facets, you may be satisfied that there has been more stones in the gall bladder, and the chances are that there are more present and that the patient will suffer successive attacks of pain until they are all discharged.

When you ask why this man with such a large number of gall stones, so different in size, some small and others comparatively large, did not exhibit spells of biliary colic, what shall I answer? It is possible that some have passed. It is not improbable that the attacks of flatulent dyspepsia may have been associated with the passage of biliary calculi. It is a mistake to suppose that the escape of gall stones is always accompanied by the severe symptoms usually described. It is customary to say that the symp-

toms of the passage of a stone through bile ducts are, violent pain in the region of the gall bladder, shooting through to the back and up to the shoulder, nausea and vomiting, followed that evening or the next morning by jaundice, high-colored urine and putty-colored stools. The attack passes off, leaving behind some tenderness in the region of the gall bladder. These are the symptoms of the passage of a large stone. Time after time have I found gall stones after attacks of sharp pain in the epigastric region, unattended by the slightest jaundice or the presence of bile pigment in the urine or its absence in the stools. In these cases the gall stone has been so small and passed so quickly along the gall duct that it has simply given rise to a transient attack of pain, but the retention caused has not been of sufficient duration to cause jaundice; or else, just as we have here seen, the bile may have been able to escape along the side of the stone, so that there was not at any time complete obstruction. Last spring I obtained from a patient who had suffered from a series of attacks of pain in the epigastrium, which had been called wind colic and which had not been accompanied by jaundice, twenty or twenty-five stones in three or four attacks. I do not know how many stones may have been passed during the two years that she had suffered from these attacks. Whenever a patient complains of obscure pain in the region of the epigastrium, the fæces should be washed and examined in the manner I have described, for it may be a case where small gall stones are passed through a large and healthy duct without giving rise to obstruction sufficient to cause jaundice. In some people the gall bladder is very tolerant of these foreign bodies, while in others a single calculi will cause repeated attacks of colic. I have seen a patient with a single smooth, round calculus who would have, at very short intervals, severe attacks of pain, followed by jaundice. The stone would slip back into the gall bladder and the attack would be relieved. I think I saw him in at least a hundred of such attacks. The stone at last became wedged in the gall duct so tightly that it could not be dislodged, and the patient died. At the autopsy I found a single large, smooth stone. In other cases, as in the one before us, the gall bladder may be filled with stones and yet the patient never complain of any symptoms of hepatic derangement. This tolerance may, perhaps, be explained by the fact that the stones are formed slowly in a healthy gall bladder, in consequence of a morbid condition of the bile, and thus the parts become accustomed to their presence, until finally they remain as though they were normal parts of the body. Still it is unusual, and I am glad to have had the opportunity of calling your attention to it, and of remarking upon the singular differences that exist in regard to the symptoms of the formation of gall stones in different cases.

Paracentesis with a Capillary Canula.

I shall now ask your attention to a very simple mode of performing paracentesis in ascites.

This lady has serious organic valvular disease of the heart. She formerly had considerable albumen in the urine, and occasionally a few tube casts. She has great œdema of the extremities, and enormous ascites. Her habits are perfectly unexceptional. Her father is living and healthy. Her mother has chronic bronchitis. There is no hereditary disease. She is married, and has had two miscarriages, at the end of the fourth month. I have inquired carefully, but have been unable to find any evidence of infection of the system. Here you see great distention of the abdomen. There is fluctuation on palpation. There is dullness in the dependent portions, resonance in upper part, and alteration of the position of dullness by changing the position of the patient's body. In other words, we have a large effusion, free to move, in the peritoneal cavity. With this there is great œdema.

Under treatment in the hospital, last fall, she was immensely improved. She was placed in bed and given a diet of skim milk for three or four weeks. She was also put upon the use of iodide of potassium and digitalis. Under this treatment her heart came down to a regular steady beat. It is now 80 in the minute, and perfectly regular. Of course, the murmur (a double mitral and aortic systolic) remains. The albumen in the urine has disappeared, showing that it was a congestive albuminuria and not due to true Bright's disease. The œdema of the legs also vanished; but while this was the case, the girth of the abdomen diminished only a few inches. We are now face to face with this chronic peritoneal effusion, which we find somewhat difficult to explain, in the absence of any kidney trouble. It cannot be due to nervous stasis, a result of cardiac weakness, for then the œdema of the legs would not have disappeared. This effusion must result from some trouble within the abdominal cavity. Of course, our suspicions are that it is associated with an affection of the liver; but we cannot determine the condition of the liver, until we have withdrawn the fluid.

A few days ago I drew off some of the fluid for chemical and microscopical examination. This is the report: "Amount of fluid examined, one pint; light greenish yellow in color; specific gravity, 1.020; alkaline reaction; it contains albumen and chlorides, but no urea, no sugar, and no ovarian cells." To-day I propose to repeat this operation, on account of the cardiac trouble. I do not wish to rapidly remove the support which this effusion gives to the abdominal vessels, as would be the case if I used a large trocar. I propose to use this capillary canula and trocar (Dr. Southey's). It consists of a delicate steel trocar, passing through a silver tube which has numerous little fenestra in its sides. A little plate of silver slips over the tube and is held in place by a cap which is screwed in this way, so that there is no danger of the canula slipping into the abdominal cavity. I shall now attach this small rubber tube to the canula, and pass the stilet through the side of the rubber. After freezing, with ice, the point at which I intend to make the puncture, I introduce the trocar and canula, place the lower end of the rubber tube beneath the surface of the water, withdraw the trocar and slip the rubber tube far enough on the canula to cover the little opening made in its side. This will draw off the fluid at the rate of a few ounces an hour. Paracentesis performed in this manner is as simple as a

hypodermic injection. In cases of extensive pleural effusion, where you fear sudden death from a rapid removal of the fluid, this offers an excellent method of operating. In those cases of pleural effusion in which death has occurred during the removal of the fluid, I think, from the reports of the cases, that it was due to too rapid abstraction of the fluid, thus bringing a sudden strain on the lungs.

I shall allow her to remain in bed, and when the abdomen is entirely emptied, I shall have an opportunity of percussing the liver, and determining whether or not my suspicion of some chronic trouble of that organ is correct.

Acute Rheumatism Complicated by Acute Endo-Pericarditis.

We have been receiving a number of Russian refugees lately. They have been unable to speak any dialect with which we are familiar, and we have, therefore, been obliged to diagnose every case by physical exploration.

This very nice-looking lady came in yesterday, evidently suffering with acute inflammatory rheumatism, as you can see at once, by glancing at the left wrist joint. This is like studying the diseases of children and animals. You will often come across cases where, either from the condition of the patient or his inability to speak your language, you will have to depend on the physiognomy, direct exploration of organs, and the use of instruments of precision, in order to make the diagnosis. The wrist joint is not much swollen, but the way in which she holds it is perfectly characteristic. Her temperature is 101.6°. There is a decided mitral systolic murmur, quite loud and rather coarse, supposing it to be recent. There is no aortic trouble. In addition to the mitral systolic, I hear a faint mitral pre-systolic murmur, showing that there is a little roughening as well as insufficiency of the mitral valve. With this there is quite a distinct, churning, friction sound at the point of the heart. We have, therefore, an endo-pericarditis. Pressure over the heart is painful. The hands and the joints of the lower extremities are also affected with the rheumatic inflammation.

What is the treatment? We have moderate fever, acute rheumatic poly-arthritis, and acute endo-pericarditis. The tongue is dry and brownish in the centre. In cases of this kind, where the heart is already affected, I do not like to depend upon salicylic acid or the salicylates. My observation has been adverse to their use in complications of a rheumatic character. In simple acute rheumatism (rheumatic fever with poly-arthritis), I like to try the salicylates, and I give them a fair trial for a few days. If they do not then do good, it is not worth while to continue their use.

In this case the fever is moderate, and does not constitute a serious complication. As long as the fever is under 103°, it is of no consequence. The worst complication is the cardiac trouble, which, unless relieved, is going to leave this woman crippled for life. We must resort to such remedies as will, as quickly as possible, affect the heart. I therefore placed this woman upon calomel, opium and digitalis, giving her quinine, in moderate doses, by the rectum. She has received eight grains three times a day, dissolved, by the aid of a few drops of dilute sulphuric acid, in three ounces of liquid. When necessary, it was guarded by a few drops of the deodorized tincture of opium. She was given the following pill:—

℞. Hydrarg. chloridi mite,
Pulv. opii,
Pulv. digitalis, āā gr. ¼. M.
Ft. pil. No. 1.
Sig.—One every four hours.

This will, in the course of four or five days, slightly touch the gums, which is the condition I wish to produce. Over the cardiac region I shall place a blister, four inches square. followed in a few hours by a poultice, and afterwards dressed with diluted resin cerate (resin cerate, 1 part, cosmoline 2 parts). The affected joints will be painted with iodine, morning and evening, and wrapped in raw cotton or wool. She will receive a light diet of gruels, broths, and milk diluted with an equal part of water. Of these she can have as much as she will take. She may also have a little weak lemonade. It will be interesting to watch the course of this endocarditis. Her general appearance is more favorable than we might have expected. The moderate fever and the absence of nervous complications justify us in hoping that we shall overcome the cardiac trouble.

Medical Societies.

PHILADELPHIA LARYNGOLOGICAL SOCIETY.

Stated meeting, held at Dr. Isaac Barton's, No. 128 South Fifteenth street, on Friday evening, March 24th, 1882. Dr. J. Solis Cohen in the chair.

Dr. John H. Musser exhibited a case of Primary Laryngeal Tuberculosis, of which he gave the following history:—

James Toole, æt. 22, weaver of upholsterers' goods. Smokes moderately: habits good otherwise. Nine months ago hoarseness began and gradually increased, so that, on the occasion of his first visit to me, March 1st, 1882, could not speak above a whisper. There was no soreness, and his general health was very good. Six weeks previous to the first visit he first noticed soreness in the larynx, and in a short time speaking, coughing and swallowing became very painful. The soreness continued as a raw feeling; cough was hacking at times but generally loose, with mucous and muco-purulent expectoration. At times he suffered from dyspnœa; it was worse when going to bed. He lost flesh, and his general health failed; he never had fever. Laryngoscopic examination revealed a congested epiglottis, œdematous false cords, swelling of the mucous membrane of the arytenoid cartilage, with possibly ulceration of the left cartilage. True cords were congested.

Applied, by insufflation—

℞. Iodoform, ʒj
Morph. sulph., grs. v
Pulv. acaciæ, ʒ iij. M.

Occasional blister externally. Pain relieved by

the application so that he could speak and swallow without any discomfort; appetite returned, gained in flesh, and his general health improved. Internally took ol. morrhuæ cum syr. calcis, lacto-phos.

Remarks were made upon the case by Drs. McCoy, McCracken and Cohen. The latter observed that the peculiarity in this case was the disease commencing in the arytenoid folds and extending upward.

Dr. Isaac Barton read a paper on "The Glycerole of Ergot in Chronic Hypertrophy of the Tonsils."

In the discussion which followed Dr. Sajous stated that he had tried both ergotin and iodine by injection into the gland, without result. He found that the injection would frequently run out of a lacuna.

Dr. Cohen stated that his success with this form of treatment was not favorable, and that he had some fear of it. Of late years he has been using the galvano-cautery with good results.

Dr. A. W. McCoy has for some years made use of London paste, with which he has been successful.

Dr. Isaac Barton, in closing, remarked that he had previously tried both iodine and ergotin without favorable results, as the injected liquid frequently escaped by a lacuna, but that this did not occur with the glycerole of ergot.

Plastic Splints in Surgery.

Dr. Samuel N. Nelson presented an inaugural thesis on this subject to the Faculty of the Medical Department of Harvard University, *Annals of Anatomy and Surgery*, in which he describes the mode of preparation of the various plastic splints.

Starch Bandages were introduced in 1834, by Baron Seutin, of Belgium. The starch is prepared for use by boiling in water a few minutes, and should be of the consistency of that used by laundresses. The whole limb is enveloped in a layer of cotton wadding, which is thickly laid along and over the osseous prominences; a bandage saturated with thick starch is then firmly applied, and others added, according to the strength required. The whole is completed by starching the outside of the last bandage. Until the starch is thoroughly dried, which usually takes from thirty to forty hours, owing to the amount of moisture necessarily included, a temporary wooden splint may be applied to prevent displacement as far as possible. The drying may be somewhat hastened by the use of hot sandbags. The starch splint is light and inexpensive, and the materials are always at hand. It is, however, sticky in manipulation, and, to give sufficient firmness, usually requires stiffeners, such as pasteboard, hoop-iron or wire. These may be added to any of the plastic splints, but are seldom required with plaster, and only when much additional strength is necessary.

Compared with the plaster splint, starch has the disadvantage of hardening only after many hours, instead of a few minutes, and requiring extension until dry. And, as it contracts in drying, it is not so safe.

Dextrine.—Dextrine, which is preferred to starch by Velpeau, and which is in many respects superior to it, is a substance obtained by the continued action of diluted sulphuric acid upon starch at the boiling point. It is prepared by thoroughly mixing with it spirits of camphor or brandy, in the proportion of ten to six, and adding four parts of warm water, when the solution will be about the consistency of molasses. The application is similar to that of starch.

Glue and Chalk.—The glue and chalk bandage is recommended by Bryant, who uses equal parts of gum-arabic and precipitated chalk, made into the consistency of thick paste by the addition of boiling water gradually stirred into it. This becomes firm sooner than starch, and is more solid.

Glue.—The glue bandage has been adopted by Mr. C. de Morgan, in the Middlesex Hospital. He uses the best French glue, dissolved in water, to which alcohol is added to induce more rapid drying. The application is similar to that of the starch bandage.

Glue and Oxide of Zinc.—Dr. R. J. Levis, of Philadelphia, introduced to the American Medical Association, in 1876, a dressing made of ordinary glue and oxide of zinc, and said that the glue, by this means, hardens with rapidity. "Too much oxide of zinc must not be added, lest it make the splint brittle and liable to crack." Any kind of texture can be used with the plastic material. This makes a light, neat, firm dressing, and where not much tendency to displacement exists, as in fractures of the forearm, is desirable. It sets slowly, however, as compared with plaster, is less porous, and contracts considerably in drying.

Paper.—Paper splints also serve a useful purpose. They are made by soaking pieces of shaped pasteboard and moulding them to the limb, around which are wrapped strips of stout paper, wet with water or with starch. It is less strong than the glue and oxide of zinc bandage, is slow in drying, and only exceptionally to be recommended.

Silica.—The silica bandage is made of the silicate of potash, or soda, dissolved in an excess

of caustic alkali. The late Dr. T. B. Curtiss, of Boston, reported in the Boston *Medical and Surgical Journal*, for June 28th, 1877, that the silicate of potash is preferable to the soda salt, which requires very long to dry. A coating of the solution is applied with a brush to a dry roller bandage over the limb, and two or three more layers are added, to give sufficient strength. The solubility of the silicate in water is an advantage, for it renders the removal of the bandage easy. It dries quicker than starch, but less quickly than plaster. It is lighter than plaster, but contracts in drying, and is not so safe. It is also very sticky and disagreeable to manipulate.

Tripolith.—Prof. Von Langenbeck recommends tripolith for surgical purposes. It consists of lime, silicon, and oxide of iron. It hardens sooner than plaster of Paris, and when once dry and hard never absorbs any moisture. Dr. Nelson has experimented with this article, and does not find it possessed of the advantages claimed for it.

Plaster of Paris or gypsum, the hydrated sulphate of lime, is prepared for plastic use by slowly heating it to between 212° and 392° F., to drive off the water of crystallization. It combines with water, forming a hydrate, and crystallizes or "sets," becoming in a few minutes quite firm and hard. The plaster must be of fine quality, such as is usually furnished for dental use, freshly calcined and carefully protected from the absorption of moisture from the atmosphere. The kind of cloth employed is of importance, both for the immediate and ultimate success. It must be sufficiently strong and of such a texture as to take up and retain plaster easily. After many experiments with different kinds of cloth, Dr. Marcy has decided that the cheap bleached cotton cloth used for printed calico, meets more of the demands than any other, if used before it has received the dressing. To procure cloth at this stage of manufacture one must go to the bleacheries. It is then free from the vegetable oil with which each fibre was covered, and has not received the filling of earthy and starchy compounds necessary to give the firmness required in finishing, and is equivalent to the surgeon's absorbent cotton. It is the right texture to take up plaster and retain it. It gives the maximum of strength, and when applied it forms a kind of felt, which does not crack, but rather wears out if subjected to friction, as over the heel.

Strangulation, and even fatal gangrene, have been known to follow the improper application of fixed dressings; but this should not prevent their use when their advantages are so very apparent. If it does occur, gangrene is sudden and unheralded.

The patient should be visited within twenty-four hours, and careful inspection of the limb be made. The bandage should be removed at once if there s swelling of the fingers or toes left exposed; if they become purple, benumbed, or cold, the circulation is impaired, and there is compression. Even without these symptoms, continued pain is sufficient indication that something is wrong.

In regard to the time when a plaster splint should be applied, although many able authorities prefer to wait until after the swelling has subsided, yet there is abundance of evidence, from Larrey, Velpeau, Seutin, Erichsen, St. John, and Marcy, to show that it can be applied immediately after the injury, not only with perfect safety, but with better results. The plaster dressing is applicable to all fractures of the long bones, of the clavicle and ribs, and to acute fractures of the spinal column.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——The Special Therapeutic Value of Hyoscyamine in Psychiatry. By C. H. Hughes, M.D., St. Louis. A reprint from the *Alienist and Neurologist*, April, 1882.

——Observations on Surgery in Children. By Edward Borck, M.D., St. Louis, Mo., comes to us as a reprint from the St. Louis *Medical and Surgical Journal*. June, 1882.

——Observations on Hemiplegia. By A. D. Rockwell, A.M., M.D. Reprint from *Medical Record*, April 29th, 1882. This is a practical paper, based on the observations made by the author during an extensive experience.

——Galvano-caustic Method in Nose, Pharynx and Larynx. By Dr. J. Solis Cohen, of Philadelphia. This pamphlet, received with the compliments of the author, contains the address delivered by him before the International Medical Congress.

——Preliminary paper on the determination of a standard of color-sense for reflected color by daylight; with a graphic description of the individual limits and average results of sixteen cases. By Charles A. Oliver, M.D., of Philadelphia. Reprint from the *Archives of Ophthalmology*. Vol. XI, No. 1. March, 1882.

——Carotid Compression and Brain Rest. By J. Leonard Corning, M.D., member of the New York Neurological Society. This is a small pamphlet of 39 pages, intended mainly to illustrate an instrument devised by the author, to combat sleeplesness and other conditions where there is too much blood in the brain, by means of compression of the carotids.

——The subject of the diagnosis of Pott's Disease of the Spine before the stage of deformity, is treated of in a reprint from the Boston *Medical and Surgical Journal*, by Dr. V. P. Gibney, of New York city. The writer has had a large experience in this disease, and the cases he records are instructive and merit the attention of surgeons.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

A MODEL INFANT ASYLUM.

Few subjects interest the student of public medicine more than the efforts made in various directions to preserve infant life. The special value which attaches to these projects arises from the excessive mortality at that period of life. The first year is by far the most dangerous of any, and the first decade counts three times as many victims as any other. Hence, if we ever expect to bring public health up to what it should be by our theories, we cannot devote too much attention to the hygiene of infancy.

The statistics of all countries show that the percentage of deaths among illegitimate is very markedly higher than among legitimate children. Hence, the former more particularly demand the early attention of the hygienist and philanthropist—for we hope no one who reads this will be found so bigoted and hard hearted as to say that these helpless creatures are the less deserving of care because of the misfortune or sin of their mothers.

This increased mortality is shown, on investigation, not to depend in any way on greater inherent feebleness in these infants—if anything, they are rather more favored in physical, as they often are in mental endowments, than those born in legitimate unions—but to the lack of proper care to which they are subjected, owing to the circumstances of the mother. They are often exposed after birth, or the surroundings of parturition are injurious. Hence no charity could be more called for than one which would diminish the loss of life by preventing these desertions.

Of the various institutions known to us which aim at this result, the New York Infant Asylum appears to us to be based on the most judicious principles. An infant is received, at birth or soon after, with its mother. The latter should accompany it, not only to supply the infant its natural food, but for the moral influence which will be exerted upon her. The names of both mother and child are regarded as absolutely confidential; each is treated with consideration and respect, and not as criminals. The result of this is that in most instances the mother is rescued from a life which, if pursued, would surely end in her moral and physical destruction.

After a period varying from six months to two years, the mother leaves the institution, a proper position, in which she can make a living, having been found for her. The child is then placed with some respectable family, adopted by them, and grows up a respectable and valuable member of society. The greatest care is exercised that such foster parents are persons of good character, who will have a real interest and affection for the child.

In connection with the Asylum, the city department of which is at 10th Avenue and 61st St., New York, there are two "country homes," one at Mt. Vernon, West Chester Co., the other at Flushing, L. I.; to these the infants are distributed, and with the most favorable effects on their health.

The only difficulty which the institution encounters in carrying out its plans is in finding a sufficient number of families of the right kind to adopt the children, and this, no doubt, arises from the ignorance that children can be there ob-

tained for that purpose. As the President, Mr. Clark Bell, justly observes, in a recent address:

I am fully convinced that if public attention was properly called to the number of children for adoption this Institution can furnish, and be made to see how favorable the legal provisions are for protecting the foster-parent in the title custody of the child, we should easily meet the present difficulty, and enlarge very greatly our sphere of usefulness.

We would ask the attention of our readers to this Institution, and advise them to study its details, not only because we believe it to be a model of its kind, but we think they should aid its work, by letting it be known to respectable families among their patients who wish to adopt children, that they can be obtained under the most favorable provisions from this Asylum.

Those who wish for full particulars may address Mrs. Catherine M. Van Auken, 421 Fifth Avenue, New York City, the lady to whose earnest devotion and intelligent care the Asylum owes both its origin and much of its usefulness.

Notes and Comments.

Albuminate of Mercury in Syphilis.

Mr. H. W. White, in the Glasgow *Medical Journal*, May, 1882, relates the histories of four cases of syphilis which occurred in the Glasgow Royal Infirmary, and were treated with albuminate of mercury. In all of the cases secondary syphilis was clearly present, and they all improved rapidly and were discharged well, the first case in about forty-five days, the second in less than a month, the third about twenty-five days and the fourth nearly two months. In this last case there was syphilitic iritis and loss of sight, with an eruption of psoriasis on face, neck and back. He was at first treated with the bichloride of mercury and iodide of potassium, but seemed to get worse, when the injections of albuminate of mercury were resorted to, and he immediately commenced to improve, but, unfortunately, was compelled to leave the Infirmary when he had received but seven injections, and before a cure had been effected. In the first case thirteen injections, equivalent to $1\frac{3}{4}$ gr. of the bichloride of mercury, were given, when, owing to commencing soreness of the gums, it was stopped and iodide of potassium with infusion of quassia substituted. The second case received six, one each night, when the iodide was substituted. The third received a total of six injections, each one containing $\frac{1}{6}$ gr. of the bichloride. The solution of the albuminate was injected deeply into the deltoid muscles, and no abscess or suppuration resulted. It was freshly prepared every day, by dissolving 2 grs. of the bichloride of mercury in ℥j of water; to this a solution of one part white of egg to two parts water was added, until all the mercury was precipitated as an albuminate; a saturated solution of common salt was then added, drop by drop, until the precipitate was dissolved, and the solution made up, so that 5 minims contained $\frac{1}{12}$ gr. of the bichloride.

Undescended Testicle.

At a recent meeting of the Medico-Chirurgical Society of Edinburgh (Edinburgh *Medical Journal*) Dr. Heron Watson showed an undeveloped and undescended testicle which he had just removed from a patient over forty years of age.

The man had recently begun to suffer pain on the side on which the testicle had not descended. He also felt as if some body was endeavoring to come down at the time the pain was worst. The nature of the case was evident when an examination was made. He was, therefore, advised to submit to the removal of the atrophied testicle and sac, and so have the abdominal serous continuation into the inguinal canal cut off, thereby preventing hernia, to which he was liable in that condition. The operation had been done antiseptically, and the case had gone on well.

Iron Ring Around External Genitals.

Dr. R. L. Batterbury thus writes in the *British Medical Journal*, April 29th, 1882: On the evening of March 10th I was summoned to see an old man, aged 66, whose penis and scrotum were enormously swollen and œdematous; and on my inquiring the cause, he pointed out to me that he had an iron ring around the root of the penis, behind the scrotum. He was in a good deal of pain, but had no difficulty in micturition, and he had been trying to remove the ring by filing. With the aid of an assistant I succeeded, after an hour's hard work, in filing through the ring and removing it. To accomplish this we held the ring firmly by means of two strong pairs of forceps, and prevented the file from doing injury to the soft parts by inserting a thin iron chisel between the ring and the skin. The ring was a quarter of an inch thick, and an inch and a half in internal diameter. The account the patient gave was that when gardening, on March 4th (six days previ-

ously) he had dug up the ring, and out of curiosity had tried it on. Finding that he could not remove it, owing to the swelling of the parts, he had unwillingly sent to me. The ring had ulcerated through the skin, causing a deep wound, and imbedding itself partly in the soft tissues. Under the use of hot fomentations and lead lotions, the œdema soon disappeared, and the wound healed.

I may add that there were no signs of insanity in the man.

Chionanthus Virginica.

Dr. John A. Henning thus describes this recent addition to the materia medica, in the *Therapeutic Gazette*. It is a small shrub, growing from 5 to 10 feet high. It is found all the way from Pennsylvania to Georgia, growing mostly in sandy and hilly land. The flowers are almost snow white, the leaves are from 4 to 6 inches wide, and from 10 to 12 long. The fruit is berry-like in appearance and contains the seed. It is also known as snow flower, old man's beard and fringe tree. The bark of the root is the part used for medicinal purposes. It possesses tonic, diuretic and diaphoretic properties, and is a mild aperient. It might be called an alterative, in the true sense of the term, because it promotes nearly all the secretions, without producing debility. It is an excellent remedy in jaundice, and makes a good tonic in that form of dyspepsia where the mucous membrane of the stomach is in an atonic condition, and the liver and small intestines are torpid. Owing to its tonic power over the stomach and other viscera, it may prove valuable in the atonic stages of scrofula and syphilis. It has been found beneficial in herpes, eczema, psoriasis and roseola, but it must be used for a long time in such cases.

However, after repeated experience and close observation with this medicine, I think that in jaundice and hypertrophy of the liver it is reliable in nearly all cases, and doubtless stands at the head of all other remedies for those pathological conditions. Its selecting tendencies are for the liver, kidneys and skin, stimulating those organs to normal action and renewing innervation. To go beyond this, I think we have other remedies that will supercede it.

When we administer any remedy, we must know its action and behavior in the system, and unless we know this, we certainly are practicing more or less empiricism. Now-a-days it is very common, especially with new remedies, to overrate them, and to recommend them in certain diseases in which they have no influence. The profession should be more guarded, and in giving any remedy, we must closely observe its action and behavior in the system.

Excretion of Nitrogen by the Skin.

Dr. J. Byrne Power, in the Dublin *Journal of Medical Science*, May, 1882, gives an account of experiments performed on himself and others, to determine the power of the skin to excrete nitrogen. This has been a much mooted question among investigators; some holding the ground that the skin does not excrete nitrogen, while others maintain the opposite view. Indeed, in 1858, Funke, by experiments on himself and two pupils, claimed that he not only found nitrogen in the sweat, but also proved its existence there as urea. Dr. Fleming substantiated these results by experiments. As a result of his experiments, Dr. Power believes that under ordinary circumstances the excretion of nitrogen by the skin is very small indeed, even in cases of gout and Bright's disease, where he expected to find it present in larger amount; and, in conclusion, observes that though he found nitrogen to be excreted by the skin in all cases, yet the quantities were so small that he does not believe the cutaneous excretion can ever act vicariously of the renal to any appreciable extent.

This is a very important question in its relation to the rapidly increasing fatality from Bright's disease, and it is a field into which original investigators ought to turn their efforts.

Pelletierinum Tannicum.

The alkaloid *Pelletierinum*, lately extracted from the *cortex radicis granati*, is, according to Dr. H. Witt (St. Petersburg *Medical Weekly Journal*, April, 1882,) the most certain of all our remedies for tapeworm. In five cases, in which for a number of years all the usual remedies, even extr. felic. marisarth., had proven themselves to be unsuccessful, about twenty-two grains of pelletierinum tannicum followed by a tablespoonful of castor oil had the effect that the dead tapeworm appeared unbroken in the stool. The remedy is easily administered, as it is perfectly tasteless.

Hereditary Lead Poisoning.

The *Medical Times and Gazette* says, that Dr. B. Rennert, of Frankfort, claims to have noticed a peculiar form of hereditary lead poisoning, viz., hydrocephalus, or a disproportionate size of the head, but without signs of rickets or any special tendency to convulsions. His observations were made on eleven families, with seventy-nine

children, among the inhabitants of a village in Hesse, where most of the population are employed in the glazing of pottery, and suffer largely from chronic lead poisoning. Half the children died in the first few years of life, and the survivors suffered as described.

Correspondence.

Corrections.

Ed. Med. and Surg. Reporter:—

I find in the abstract of my paper, Subjective Traumatism of the Eye, read at the last meeting of the Pennsylvania State Medical Society, and reported in your Journal, May 20th a few corrections to make.

The statistics are made up from the Reports of the ophthalmic hospitals and ophthalmic work in general hospitals of the leading cities of the United States, not from the *Dublin* hospitals.

In place of Dr. *Lorenz* read Dr. Loving, and for Dr. *Erbmann* read Erismann.

The emmetropic eye should theoretically be healthy, not *structurally* healthy.

The emmetropic eye should be only liable to objective traumatism, not *subjective* traumatism.

Thanks, for the space already granted, and for these corrections. Wm. T. Little, M.D.

Expert Testimony.

Ed. Med. and Surg. Reporter:—

I read your editorial on "Subpœnas to Medical Men," in the number of the 13th ult. with interest. It is all true as to the right of medical men, when subpœnaed, to testify as to matters of fact. But it is not all the truth when expert testimony is called for; in other words, when an opinion is called for which can be given only by a person who has professional knowledge, obtained by long continued and expensive studies, supplemented with large experience, and upon which knowledge the witness is dependent for his support; if the court cannot get along without such testimony, justice requires that it should be paid for in proportion to the value of the witness' time and professional knowledge when employed privately. If expert testimony is not worth this it is worth nothing. When courts need the assistance of a legal gentleman fifty dollars does not secure very much.

I have known a physician on the witness stand in a New Jersey court, while testifying to facts, refuse to answer a question as to his opinion on a medical point, unless he had a fee. He was not compelled to answer, as he would have been in this State. A person should not be obliged to give expert testimony unless paid a proper professional fee. This entire matter is worthy the attention and action of the State Medical Society.

If experts could be called by courts, instead of the parties to a trial, justice would be promoted and the profession elevated. Whoever can bring about such a procedure in our courts will be a great public benefactor. Justice.

Danville, Pa., May 24th, 1882.

News and Miscellany.

Proceedings of the American Surgical Association.

The Third Annual Session of the American Surgical Association was held at the College of Physicians at Philadelphia, beginning on Wednesday, May 31st, and continuing until Friday, June 2d.

Wednesday, May 31st.

The meeting was opened by the President of the Association, Professor S. D. Gross, M.D., LL.D., D.C.L., with the following remarks:—

Gentlemen of the American Surgical Association, the Executive Committee in charge of this meeting, which I now formally open, has assigned to me the pleasing duty of welcoming you to our city. It would be needless for me to multiply words, but this I may say, that as true and loyal members of our profession we should spare no efforts to pass the time agreeably and profitably.

A union like this may be looked upon both in a practical and in a social aspect. As you will see from the programme placed in your hands by the Executive Committee, the first object has not been overlooked. and that abundance of work has been provided.

Hardly less important are the social features and the cultivation of kindly feelings. If our meetings were only for the discussion of scientific papers and the presentation of cases, they would indeed be cold and tame, if not heartless affairs. There is a wealth of feeling in a savory lunch, a stately pillow, a kind reception, a glass of generous wine. The Executive Committee have laid full stress upon these points. Owing to the amount of work and the limited time, they have made no arrangements for steamboat excursions, drives through our beautiful park or for visits to Cape May or Atlantic City.

The question has been asked, perhaps pertinently enough, what need is there for such an organization as the American Surgical Association? The answer to this question is not difficult, at least, I do not find it so. We have in the United States no fewer than sixty thousand medical men; among these there are a large number of surgeons, whose knowledge and skill would do honor to any country. To unite these men into one harmonious whole, for the benefit of all, is one of the main objects of this Association. Our object is not to interfere with the American Medical Society, but we wish to strengthen that body, to rouse it from its Rip Van Winkle slumbers and infuse into it new life. We cannot injure it. We can only injure ourselves if we fail to do our duty.

We live in a fast age. Progress everywhere stares us in the face. The surgical profession was never so busy as it is at the present moment, never so brilliant, never so full of bold expedients, never so beneficent in its results. Many of our best men are busy in perfecting our knowledge. Theory is giving way to fact. The whole field of surgery, from the structure of a boil on a man's face to an amputation through the hip joint, is undergoing revision. The progress of surgery challenges the respect

and admiration of the world, and although it has not reached its finality, it is as near perfection as we can hope to make it. Surgical pathology was never so sedulously and successfully cultivated. The importance of physiology to the practice of surgery is daily becoming more apparent.

Since our last meeting, death has been busy. Some of our best and most esteemed men have fallen by the wayside. There are seats in this Association which will never again be filled. The list comprises, Wm. Warren Green, of Maine; Hugh W. Brock, of West Virginia; John W. Wood, of New York; John T. Hodgen, of Missouri; and J. C. Huges, of Iowa. To these may be added the name of H. Lenox Hodge, who died early last summer, greatly regretted by all who knew him. The departure from among us of so many prominent men at this early period of our organization, is a calamity, indeed. I should suggest that the Association take proper action in this matter. That this meeting will be conducted with energy, in the best interests of the profession, I feel assured.

The remainder of the morning session was occupied with the reading of the minutes, admission of new members, and the transaction of other business.

AFTERNOON SESSION.

On the reassembling of the Association, Dr. J. L. Cabell, of Virginia, read his paper

On Sanitary Conditions in Relation to the Treatment of Surgical Operations and Injuries.

He said that he would have special reference to external and local conditions, rather than individual peculiarities of temperament. After alluding to many conditions, he referred to the statement of Dr. W. A. Hammond, that he had noticed that wounds heal with greater rapidity when sunlight is allowed to reach them, than when they are covered, but the speaker thought the accuracy of this view might fairly be questioned, in view of the amount of evidence as to the rapidity with which wounds heal under certain antiseptic dressings; but as to the general sanitary value of sunlight there can be no doubt. Purity of the air, water, and food were then noticed.

The plan suggested by Stephen Smith, of New York, by which the primary or anti-pyretic may, by the use of preliminary antiseptic treatment, be extended long enough to give time for the subsidence of shock, while inflammation and traumatic fever are averted, was then alluded to. This primary period may sometimes be extended for a week or longer.

Many statistics were given, to show the influence of septic diseases on the mortality after operations. The Pennsylvania Hospital, in Philadelphia, was given as an illustration of the great triumph of hospital sanitation. From 1875 to 1879, there were performed 108 amputations on 100 persons; of this number 17 died; five deaths took place within 36 hours; four were from tetanus; two from exhaustion, etc.; three from secondary hemorrhage; two from delirium tremens and one from cerebral effusion. During the five years referred to, there was not a single case of pyæmia. This result is attributed to the perfect forced ventilation by the fan, to scrupulous cleanliness, the free use of carbolic acid, and to the system of dressing wounds with flowing water. In the same Institution there were, from 1879 to 1882, four deaths from pyæmia, and one from diffuse cellulitis, out of 28 amputations. The fatal cases were cases of "Railroad crush," which goes far to relieve the hospital from the opprobrium of so large a percentage of deaths from septic diseases.

In the Episcopal Hospital, in this city, there were during the past seven years 80 amputations, with 17 deaths, only one of which was from pyæmia.

In regard to amputations in private practice and Cottage hospitals, the Doctor said the statistics of amputations in private practice and in cottage hospitals, in rural districts, when compared with those of the city hospitals of the usual capacity, due allowance being made for various other influences that determine the results of operations, do not warrant the sweeping conclusion that large hospitals, even those constructed on the block system, with several stories, are *necessarily* liable to outbreaks of septic diseases, or that the mortality must necessarily be greater than in private practice in the same localities, and among the same classes of the population.

The observed sanitary defects of any given hospital will almost certainly be found to be due to faulty location, faulty plan of construction, or to remediable defects of administration. Septic diseases are, indeed, likely to arise in a ward, whether of a large or small hospital, in which a number of surgical cases with open wounds are brought into proximity with each other; but if overcrowding be prevented, it is possible to prevent the spread of these diseases by adequate ventilation and perfect cleanliness in its most comprehensive surgical sense.

In order to prevent the occurrence of septic disease in wards where there are patients with open suppurating wounds, they should be diluted with non-surgical cases. Cleanliness, in its most comprehensive sense, must be enforced; no sponges should be allowed in the wards; no person who has spent some time in the dead house should be permitted to come into a surgical ward, much less assist in any operation, until he has been thoroughly washed and has changed his clothing; patients with fetid ulcerations, especially of a cancerous nature, should be isolated; not more than half of the patients in any ward should have suppurating sores, and under all circumstances, overcrowding must be avoided.

A large part of the paper was devoted to the subject of antiseptics in the treatment of wounds, and especially in ovariotomy. The following were the conclusions which the Doctor presented:—

Septic complications have heretofore been the most fruitful causes of mortality after operations in hospitals, where their malignant effects are observed after secondary, as well as after primary amputations.

Much may be done to prevent the development of septic poison by careful and untiring attention to sanitary precautions, including all the details of personal and hospital hygiene.

After securing all that can be accomplished by patient and scrupulous attention to sanitary arrangements, with a view to render the atmosphere of a hospital comparatively aseptic, there is good reason to believe that an additional protection of great value may be derived from the use of antiseptic precautions practiced in conformity with the Listerian principle.

"Listerism," practiced *de rigueur*, while not so essential in cases of amputation, where it may often be superceded by drainage and perfect cleanliness, has achieved results in operations on joints and in treatment of "abscesses by congestion," which have not been paralleled by any other system of treatment.

The preponderance of evidence is in favor of its utility in ovariotomy and abdominal sections generally, although marvelously good results have been obtained without special antiseptics, by a careful attention to other sanitary arrangements.

DISCUSSION.

Dr. David W. Yandell, of Kentucky, said that since Dr. Keith's report of twenty-seven cases operated on without the spray, mentioned in Dr. Cabell's paper, he had added forty more with as good success as when he employed the spray. That although Dr. Keith had abandoned the spray he did not think that he had abandoned Listerism altogether, for while in a large number of cases he used no formal antiseptic, yet he used sponges dipped in hot water, and they were sometimes dipped in a carbolized solution. Dr. Keith considers thorough cleansing and drying of the abdominal cavity, and where this cannot be done, the introduction of a drainage tube, of greater value than Listerism. Mr. Tait uses the same plan.

Mr. Keith, although he had given up the use of Listerism in ovariotomy, still uses it in other operations, as in opening abscesses, removing breasts, etc.

Dr. R. Beverly Cole, of San Francisco, thought that Dr. Cabell's paper was not entirely without prejudice. He quoted Mr. Lister as saying, at the International Congress, "I have never thought, from the beginning, that this system of mine was adapted to ovariotomy, and so impressed was I with this belief that when Dr. Keith informed me of his intention to adopt it and introduce it into his practice, I strongly dissuaded him from it." He thought that the Doctor had regulated his statistics to suit his theory. He did not know that he would be any more free from this than any other man. He said that of the fifteen gentlemen who took part in the discussion of this subject before the International Congress only two came out positively in the support of Listerism. These were Mr. Spencer Wells and Mr. Thornton.

Dr. Letiévant, in a paper read, said, "I am satisfied that this theory of microscopical organisms is not the correct one. He states that when called to examine the ventilation at the Hotel Dieu at Lyons, he found the maternité surrounded by the dissecting rooms, the operating theatre, the chemical theatre and the surgical wards, yet there has never been an epidemic of puerperal fever or other infectious disease incident to the child-bearing patient. He asks, "If there be anything in this theory why have we not had an epidemic of these diseases?"

Dr. H. M. Campbell, Ga., had an experience of forty years' successful practice without the use of carbolic acid. He mentioned the operation of lithotomy as one in which great harm would be caused by closing the wound and treating it according to Lister's plan. "May we not," said he. "be mistaken in thinking that suppuration is caused by microscopic germs?" He thinks that there is a chance for a new explanation. There is nothing more established than the old saying, "Where there is irritation there will be flow"—there is congestion, the result of irritation. He believes that what occurs in suppuration is this: A sensitive part of the body is injured, the delicate sensory nerves are involved. These nerves radiate and transmit influences to the spinal centre, which is in intimate relation with the nerves controlling the blood vessels in the injured part. Thus we have all the apparatus for reflex irritation. We know that suppuration is dependent almost invariably upon the increased amount of blood in the part.

What better means have we of lessening irritation and suppuration, than cold water, a sedative to the part? What better than sedatives and opiates internally?

Dr. J. W. S. Gouly, New York, has always been a consistent anti-Listeric surgeon. In a large hospital practice, for twenty-three years, he has never used the Listeric plan. He had never treated a single wound, after amputation, by closure of the wound and the use of antiseptics. If it be true that the unfavorable symptoms which follow certain operations in conditions of this system are due to the presence of bacteria in the blood and in the wound, the Listeric plan, in his opinion, was the wrong one. It may reach the micrococci in the wound, but how is it to reach those in the blood and lymph? He doubted very much if the spray would prevent their entering the wound if they were in the atmosphere. In reference to this plan of Lister's, he has every proof that it is not Mr. Lister's. He has seen documents going to show that a Frenchman, Dr. DeClat, had, as far back as 1863, proposed the use of antiseptics in the treatment of wounds. He applied carbolic acid, gave it by the stomach, bowels, and by hypodermic injection, with the object of killing bacteria in the blood. This the speaker thought to be a dangerous practice, and of doubtful utility. He had observed several cases of poisoning due to the use of carbolic acid.

While not a Listerist, he was, like every good surgeon, a sound antiseptist. He believed in keeping the parts perfectly clean, in using water and other substances. Alcohol diluted with water has, for twenty years, been a favorite with him. All give quinine. What is quinine but a parasiticide? All use tincture of the chloride of iron and other preparations of iron; these are antiseptics. No good surgeon can be otherwise than an antiseptist. I cannot conceive of any one getting good results from closing wounds after amputation and excisions of tumors. He did not think that Listerism was going to die. It was dead. Few surgeons would long continue to use it.

Dr. R. A. Kinloch, Charlestown, thought that

some of his friends did Mr. Lister and his method much injustice, when they talked about closing wounds, as we know that drainage is a part of the practice insisted on by Mr. Lister. The illustration of his friend in regard to the operation of lithotomy, I consider rather far-fetched. When we come to this matter of carbolic acid, we find that if there be any objection to it, it is to the spray. If carbolic acid does no good, how many are ready to say that it does harm? The mortality has been lessened since the use of Listerism. The very gentleman (Mr. Keith), who excludes the spray from ovariotomy, uses it in other operations. There may not be as much danger from putting the spray into a joint or into the abdominal cavity, but if it does no good, why does he use it? Listerism has accomplished many triumphs. It is not dead. He believed that we should yet hear more of it.

THURSDAY, JUNE 1st. MORNING SESSION.

The discussion of Dr. J. L. Cabell's paper being resumed, Dr. Chas. B. Nancrede, of Philadelphia, said that he thought no one who had faithfully tried this antiseptic system would speak of it as some of the gentlemen had done. He referred to the experience of Nussbaum, who, after having tried every other means of treating wounds, adopted strict Listerian methods. There was an immediate lowering of the mortality. On returning to his old methods, the previous bad results were obtained.

Bardeleben and Billroth have performed some 300 or 400 amputations, without antiseptics. The mortality was about 29 per cent. Taking about the same number of amputations, of equal gravity, performed by Nussbaum, Volkman and others, with the antiseptic system, the mortality was 4.4 per cent.

McCuen, in between 500 and 600 osteotomies had precisely three deaths; one from diphtheria, one from meningitis, and one from some cause which he could not recollect, but it was not from any septic trouble. He had tried the antiseptic method for several years. He stopped using it for several years, but he is now going back to it.

Dr. Geo. W. Gay, of Boston, Mass., had used it more or less during the past five years, in one of the largest hospitals in Boston. He thought there was no way in which a wound could be freed from odor, or profuse suppuration checked so quickly, as by the antiseptic dressing. The advantage of Listerism in ovariotomy has been fully demonstrated. He thought that the present success of operations on the joints was due, principally, to the use of antiseptics.

Dr. R. Beverly Cole, of San Francisco, denied most emphatically, both to Mr. Lister and his method, any credit, in having rendered the opening of joints. and particularly the knee joint, admissible. Dr. E. S. Cooper and himself had practiced free opening of the joints for the past 25 years, in cases of suppurating joints, and also for the removal of floating cartilages. He had no recollection of losing a single case, and yet this was before the Listerian system.

Dr. D. W. Yandell, of Kentucky, had performed ovariotomy twelve times, without the spray, and only one died, but in a number in which he used the spray several died; but he did not say that deaths occurred because he used the spray, any more than that the others recovered because he had not used the spray.

Prof. Moore, of Rochester, N. Y., would go a step further than Dr. Yandell, and say that he thought the reason Dr. Yandell's cases had died, was because he had used the spray. He had shown in an experiment, by allowing the spray to fall on a piece of plate glass, and examining the glass afterwards, that the spray collected a large quantity of motes from the air, and deposited them on the glass. He thought the steam atomizer a most ingenious apparatus for spoiling the peritoneum.

Dr. J. W. S. Gouley, of New York, had within the last ten days opened a perfectly healthy knee joint for the removal of a needle. The patient promptly recovered. He had treated other cases of wounds of the joints, without Listerism, with equal success.

Dr. J. L. Cabell, of Virginia, with a few remarks, then closed the discussion.

Dr. Moses Gunn, of Chicago, Ill., presented the next paper on

The Treatment of Fractures of the Skull, Recent and Chronic, with Depression.

After a thorough study of the subject, he presented the following conclusions:—

1. In all recent fractures with depression, whether simple or compound, even though entirely without symptoms of compression. if there is reason to believe that the internal table is depressed, and if there are no symptoms of marked concussion or collapse, elevation of the depression should be promptly effected.

2. In chronic cases, as soon as positive, even though comparatively slight symptoms of cerebral irritation present themselves, a disk of the cranial walls, intended to include the irritating point. should be removed with a trephine of requisite size.

3. All operations and dressings should be conducted on strict antiseptic principles.

DISCUSSION.

Dr. R. J. Levis, Philadelphia, thought that it should be considered an axiom in surgical procedure that the extent of mechanical depression should more influence the surgeon in regard to operative interference, than the symptoms of compression, for the symptoms of shock and concussion may mark the ordinary symptoms of compression. If symptoms of compression are waited for, we shall often leave undone operations that should have been performed early.

Prof. E. M. Moore, Rochester, N. Y., never used the trephine if he could avoid it. He thought that from the tearing of the vessels of the diploë, which it caused, it favored septic poisoning. In dressing wounds of the scalp he utilized the hairs in bringing the edges together.

Dr. Hunter McGuire, of Richmond, Va., thought that the advice given by Dr. Gunn, that every depressed fracture, even if it is simple, should be elevated, is right dangerous doctrine. He thought that to Dr. S. D. Gross, more than to any other man, we are indebted for encouraging operative interference in compound fracture of the skull. To this almost the whole surgical world agrees, but to say that it is proper to operate in every simple depressed fracture, when no

symptoms of compression or irritation are present, is giving to every young surgeon a license to use the trephine, which would be exceedingly dangerous. If the fracture is a simple one, and the depression is not sufficient to cause symptoms of compression, it is better to wait and see if the brain will not be able to accommodate itself to this condition. He had seen a depression of one inch without any symptoms of compression.

Dr. J. W. S. Gouley, New York, described the case of a soldier in which a punctured wound of the skull was produced by the lock of a gun. He was insensible when first seen. Within two hours the trephine was applied and all the fragments were removed. Beneath the disk of bone a clot of blood was found. The depression of bone was very slight. The symptoms were thought to be due to the effusion of blood more than to anything else. In this class of cases, even if the symptoms are not well marked, he thought it wise to operate within the first thirty-six hours. He did not advocate interference in all cases of fracture, but in cases of so called punctured fracture, where there is reason to believe that the internal table is fractured. He had performed the operation a number of times with success.

He described a second case; a miner, who had been struck on the head by an angular piece of coal. He was seen only five or six days after the injury, and complained only of sore head. A small wound was found and an exploratory operation was advised. The scalp was divided by a crucial incision and there was found a slight depression. He trephined this man and removed a number of fragments which had been pressing upon the dura mater. The bone at the seat of the injury was rather white, as though it were dead or going to die. The whiteness extended, and within eight weeks a large amount of dead bone was removed. The death of the bone was thought to be due more to the original injury than to the use of the trephine. He had seen another similar case.

The Doctor described another case of fracture of the skull, two inches above the external angle of the left eye, caused by a brick-bat. The depression was large enough to allow the introduction of the tip of the finger. He did not trephine. This man is in good, general health, but within six months after the injury he was laboring under a mild form of insanity, which is now no worse. The depression still exists.

Dr. H. F. Campbell, Ga., regarded trephining as one of the most capital of all capital operations. He was not willing to admit that because the external plate was depressed, the internal plate must necessarily be broken. As had been said, punctured fractures should be trephined, but he believed that was a part of the old rule, which said "trephine when you see symptoms, but do not trephine when you do not see symptoms, *except* in cases of punctured fractures." He had had bad results from not operating in such cases. He thought the brain could withstand all kinds of aggression but compression. He had been called to see a man with an axe wound in the head, exposing the brain, and found him sitting by the fire, eating his breakfast out of the frying pan. In this case the man recovered without any bad symptoms.

Dr. W. T. Briggs, Nashville, had used the trephine a great many times. He had never regretted using it, but had regretted his failure to use it in some cases. He had frequently seen secondary effects follow untreated fractures of the skull. He did not believe that symptoms of compression arising from pressure upon the brain from depressed bone were sufficient to demand operation, because all know that the brain will accommodate itself to this depressed bone. Pressure from an accumulation of blood was a different matter. He would look for and be guided by the symptoms of irritation of the brain. A boy received an injury of the right parietal bone; there was no apparent depression. He suffered from shock and concussion, which soon passed away. He began to have twitching of the left hand and left side generally. The patient was trephined, although there were no symptoms of fracture until the scalp was incised, when a fissured fracture was found. The symptoms of irritation had been caused by a spicula of bone. The Doctor advised an exploratory incision in doubtful cases. He regarded trephining (including under this term the use of the trephine, elevator, Hey's saw, etc.) as one of the safest of all capital operations.

Trephining is also called for in bruises of the skull, to allow the escape of inflammatory products.

Dr. R. A Kinloch, of Charlestown, thought an exploratory incision increased the danger, and thought that the presumption that the patient was going to suffer from secondary complications was not strong enough to justify it. Autopsies had often shown that in fracture of the inner table, the edges have been rounded off, and scarcely a remnant of the injury is left. He was a warm advocate of conservative surgery in hese particular cases.

Prof. S. W. Gross, of Philadelphia, said he should have formulated Dr. Gunn's conclusions in the following manner: He should have accepted the second proposition unreservedly. He would modify the first conclusion, to read:—

"In all recent fractures, with depression, if the latter be moderate, whether simple or compound, the patient should be left alone. If, however, fixed and severe pain at the point of injury, febrile excitement, increase of local temperature and a commencing puffiness of the scalp supervene within a few days after the accident—signs which are indicative of depression of the internal table and the development of pachy-meningitis—elevation of the depression should be promptly effected."

In all recent fractures, whether simple or compound, attended with symptoms of compression, the trephine should be resorted to; and the same rule should apply, whether symptoms be present or not, if the depression be considerable and funnel shaped. Punctured fractures should invariably be subjected to operation.

Dr. D. W. Yandell, of Kentucky, would fully agree with the preceding speaker, if he would add in his third proposition "and the symptoms of compression persisting." All know how fleeting these symptoms sometimes are.

Dr. Moses Gunn, of Chicago, Ill., in closing the discussion, remarked, "I have nothing par-

ticular to add to what I have already said. In the outset, I stated that the propositions which I should submit might not meet with general approval. Indeed, I anticipated that they might meet with general condemnation. The discussion has taken a very wide range, but I want to call attention to one or two points. In the first place, I have made no departure from the rule, in the treatment of punctured fractures, nor have I in the treatment of compound fractures, but in the treatment of simple fractures with depression and without symptoms, I have gone a step in advance of the rules laid down by our distinguished presiding officer.

The Treatment of Transverse Fracture of the Patella, with the Object of Producing Bony Union,

was the title of the next paper, prepared by Dr. R. J. Levis, of Philadelphia.

The speaker objected to the use of the ordinary apparatus for the treatment of fracture of the patella, that they presupposed grooves above and below the patella, which did not exist in nature. These grooves could only be made by injudicious pressure. This pressure above the bone would irritate the quadriceps and tend to draw the upper fragment upward, and below the pressure on the ligamentum patellæ would tend to draw the lower fragment downward. The pressure would at the same time tilt the fragments forward. Again, on account of the ob liquity of the upper edge of the patella, it is difficult to bring the fragments in contact, for when the fragments are in contact on one side, they may be a third of an inch apart on the other.

One of the most important factors in obtaining osseous union is the restoration of the continuity of the periosteum. The reason fracture occurs most frequently at the lower third, was said to be due to the fact that the tendons of the biceps muscle and the ligaments of the patella terminate at this point, and that there is in this position a leverage over the end of the femur.

In the treatment of this injury, the Doctor advocated the use of Malgaigne's hooks, or rather the modification made by himself, which consists in separating the double hook of Malgaigne's into two.

Had never been obliged to remove the hooks. Never introduced the hooks before the tenth day. The case should be treated with cold lotions and pressure until the inflammation subsides and the time for introducing the hooks arrives. The patient should be kept under treatment for three or four months.

(The doctor then presented for examination two cases of fracture of the patella, which had been treated with his modification of Malgaigne's hooks, in which bony union had apparently occurred).

The discussion of this paper was postponed until the afternoon session. The remainder of the morning session was occupied in the reading of the records of a case by Prof. E. M. Moore, of Rochester, N. Y. The following is a condensed description of the case.

November 12th, 1875, Peter M., a convict in Auburn prison, fell from a wall, causing dislocation of the hip upon the dorsum ilii. It was reduced by manipulation. Three weeks later he fell out of bed and again dislocated the joint. This time it could not be replaced.

December 25th, pulleys, in combination with manipulation, were tried, but failed. The toes were exceedingly everted, the limbs shortened two inches, the head of the femur presenting forward instead of backward, lying just behind the anterior superior spinous process. The limb was peculiarly useless, for in addition to the shortening, the motion of the knee joint was at right angles to the normal line.

December 7th, 1877, two years after the accident, the Doctor attempted an operation for its relief. He desired, if it were possible, to bring the head of the bone into the ischiatic notch by manipulation. This would bring the knee almost to the usual line, and would lessen the shortening. After the lapse of two years he would not, of course, make the attempt to bring the bone into the acetabulum. He hoped to be able to divide the adhesions subcutaneously, by means of a peculiarly shaped knife which he had prepared. The patient was etherized and pulleys applied, but a little examination showed that there was bony anchylosis. A large osteophyte enclosed the head and secured it to the ilium.

He now made an incision below the trochanter, barely large enough to permit the introduction of the finger down to the thigh bone. The bone was cut through about one-fourth of its thickness by a metacarpal saw, both on the anterior and posterior surface. The bone was then fractured, rotated to its proper position, and a weight attached to it. The leg was brought down to within half an inch of its normal length. It was kept in this position one month. At the end of this time his condition was good. The weight was now discontinued and the limb placed on a double inclined plane. During the whole time a drainage tube was kept in the wound. Other openings formed. The treatment consisted of quinine, stimulants, good diet, and the application of poultices. The angle of the splint was daily changed, in order to create a false joint. February 3d, 1878, an apparatus was applied to keep the limb in proper position, and he was allowed to walk on crutches.

The Doctor then lost sight of him until July 22d; his sentence having expired, he was brought to St. Mary's hospital, at Rochester, where he remained until July 30th, when he died, from pulmonary disease. At the autopsy there was found that, although the bone had been separated an inch and a half, the whole space had been filled with osseous deposit. It seemed to the speaker that the growth could have been due only to a rapid and enormous production of granulation tissue, which also, in its turn, furnished an easy opportunity for the deposit of bone salts. It is marvelous that the form and size of the bone should have been so well preserved in this intermediate space.

At one time this patient presented a syphilitic eruption, for which he was given iodide of potassium and some mercury.

The Doctor then presented the specimens from this case, which were examined with great interest.

AFTERNOON SESSION.

The discussion of Dr. R. J. Levis' paper was

opened by Dr. T. G. Morton, of Philadelphia. He first used Malgaigne's hooks in 1873. The result was perfect. He had modified the hooks by separating them into a lower and an upper half, to facilitate their introduction. He saw no use in leaving the hooks longer than sixteen or seventeen days. He never applies them under four days. There are many cases where the hooks should not be used, as, for instance, in comminuted fracture.

(The Doctor here presented a case of comminuted fracture treated by the old method, in which there was wonderful union, the man having as good use of one limb as of the other.)

Where approximation could be made by slight pressure he would not think of using the hooks.

Dr. Wm. A. Byrd, of Illinois, had used, with success, Martin's rubber bandage, first applying a well padded splint to the back of the leg, and then making figure-of-eight turns around the joint and bringing circular turns around the outside of the joint, to counteract any tilting.

Dr. Bontecou had used extension by adhesive plaster, successfully.

Dr. H. F. Campbell, of Georgia, described several cases of the fracture, occurring in his practice, and also a case of congenital abscess of both patellæ, in which the boy had complete use of his limbs.

Dr. R. J. Levis, of Philadelphia, considered it impossible to penetrate the joint with the hooks. There was very little pain attending their use. He employed no particular dressing, but was careful to keep the bed-clothing from displacing them. No other method of treatment will secure such results. He had never had an opportunity of making a post mortem examination of any of these cases.

The discussion of Dr. E. M. Moore's paper was then taken up.

Dr. H. F. Campbell, of Georgia, inquired if the great proliferation of bone might not have been due to some of the peculiar traits of syphilis.

Dr. J. Ewing Mears, of Philadelphia, described a case in which he had performed subcutaneous osteotomy, for the relief of severe pain following an unreduced dislocation of the shoulder joint, and with the hope of establishing a false joint. The pain was relieved, but the autopsy, a year later, showed that osseous union had occurred.

Dr. E. M. Moore, of New York, described another case, in which the attempt to make a false joint at the hip, was followed by bony union. He did not think that syphilis had anything to do with the production of bone in the case he had described.

Dr. J. R. Weist, of Richmond, Ind., then read a paper entitled

Foreign Bodies in the Air Passages.

The paper contained the history of 1000 cases (900 of them never having been before reported) arranged in tabular form. They were collected by personal correspondence with physicians in all countries. From a careful study of these cases Dr. Weist arrived at the following conclusions:—

1. When a foreign body is lodged either in the larynx, trachea or bronchia, the use of emetics, errhines or similar means should not be employed, as they increase the sufferings of the patient, and do not increase his chances of recovery.

2. Inversion of the body and succussion are dangerous, and should not be practiced unless the windpipe has been previously opened.

3. The presence simply of a foreign body in the larynx, trachea or bronchia, does not make bronchotomy necessary.

4. While a foreign body causes no dangerous symptoms, bronchotomy should not be performed.

5. While a foreign body remains fixed in the trachea or bronchia, as a general rule, bronchotomy should not be practiced.

6. When symptoms of suffocation are present, or occur at frequent intervals, bronchotomy should be resorted to without delay.

7. When the foreign body is lodged in the larynx, there being no paroxysms of strangulation, but an increasing difficulty of respiration, from œdema or inflammation, bronchotomy is demanded.

8. When the body is movable in the trachea, and excites frequent attacks of strangulation, bronchotomy should be performed.

DISCUSSION.

Dr. H. F. Campbell, of Ga., Dr. J. Ewing Mears, of Philadelphia, and Dr. Chas. B. Nancrede, of Philadelphia, took part in the discussion, and described additional cases.

Dr. Wm. T. Briggs, of Nashville, Tenn., read a paper on

The Antiseptic Treatment of Wounds after Operations and Injuries.

The speaker made an elaborate analysis of his subject, and embodied the result of his researches in these conclusions:—

1. The germ theory of wound infection is not established.

2. The antiseptic treatment of wounds after operations and injuries is not limited to Listerism or any other special method, but is based upon broad general principles.

3. Antiseptic surgery embraces every condition or agent that tends to prevent putrefactive changes in wounds, or to remove or neutralize the effects of such changes when they have occurred.

4. All wounds are healed by reparative inflammation.

5. All wound-accidents are the result, either directly or indirectly, of destructive inflammation.

6. The antiseptic treatment of wounds, properly considered, consists, first, of such means as will restrain inflammatory action within reparative bonds; and, second, of such means as will subdue excessive action, and remove or neutralize the effects of destructive inflammation.

DISCUSSION.

Dr. E. M. Moore, of New York, fully agreed with Dr. Briggs, and described a plan of operating with exclusion of the air, by allowing carbonic acid to enter the place of operation, when it would, being heavier than the air, preoccupy the space. He had performed ovariotomy four times in this way, but two of the patients had died. He intended to continue his experiments.

The Doctor also referred to the fact that he had, on one occasion, seen a mass of coagulable lymph, as large as a filbert, lying in a wound from which the air had been excluded by allowing the bandages to become soaked with blood.

Dr. H. F. Campbell, of Georgia, spoke of the value of cinchonizing all patients with wounds. He bases its use upon his theory of suppuration. He considers that its value is due to the fact that quinine destroys spinal reflex excitability. He thinks that by quieting the peripheral excitability with carbolic acid and opium, and the centric reflex excitability by quinine, we have the best possible conditions for repair of wounds.

The Association then adjourned.

FRIDAY, JUNE 2—MORNING SESSION.

At the executive session the following resolutions were presented by Dr. D. W. Yandell, and adopted:—

WHEREAS, The American Surgical Association, in annual session at Philadelphia, on June 2d, has learned with deep regret that the Senate Committee on Appropriations has reduced the annual appropriation for the museum and library of the Surgeon General's office, from $10,000, as passed by the House of Representatives, to $5000; therefore,

Resolved, That the President and Secretary are hereby instructed to communicate to the U. S. Senate the views of this Association, as expressed at this meeting, in reference to this proposed reduction, and to state that, in the opinion of this body, such reduction would be extremely unwise, by hampering the growth of the museum and library, in which the people of the whole civilized world are deeply interested, because through these collections and the emanations from them, the knowledge of the science and art of medicine, and its application to the relief and cure of disease and injury, are vastly increased and diffused for the benefit of all mankind, and now to cripple this work, which the Government has in its power to develop, by a reduction of appropriations, would be to retard the unfolding of resources to successfully combat disease and injury, and to impair the growth of an institution which is everywhere regarded as an enduring monument of the philanthropic liberality of the American nation.

Resolved, That these collections, which are unrivaled in their richness and usefulness, are a source of just national pride, and, as they are a benefit beyond price to the whole people, for all men are subject to disease and injury, they are especially worthy of the fostering and liberal care of a government of the people.

Appropriate resolutions in relation to the deaths of Lenox Hodge, J. C. Hughes, W. W. Green, H. H. Brock, J. T. Hodgen, and J. R. Wood, Fellows of the Association, were adopted and ordered to be placed on the minutes.

The officers elected to serve during the ensuing year were: President, Prof. S. D. Gross, M.D., L.L.D., D.C.L.; Vice Presidents, Dr. E. M. Moore, Rochester, N. Y.; Prof. Moses Gunn, Chicago, Ill.; Secretary, Dr. J. R. Weist, Richmond, Ind.; Treasurer, Dr. John H. Packard, Philadelphia; Recorder, Dr. J. Ewing Mears, Philadelphia; Council, one year, Dr. R. Beverly Cole, San Francisco; two years, Dr. George W. Gay, Boston; three years, Dr. Hunter Maguire, Richmond, Va.; four years, Dr. H. F. Campbell, Georgia.

The first paper read was by Dr. J. C Hutchinson, of Brooklyn, N. Y., on Diseases of the Hip Joint, which elicited some discussion.

Dr. H. F. Campbell, of Ga., then presented a synopsis of a paper on the

Ligation of Arteries for the Cure of Gangrenous Inflammation.

The speaker had tried this method with successful results, and from his experience, he said that no limb which was the seat of traumatic, gangrenous inflammation should be amputated until after ligation of the principal vessel had been tried.

DISCUSSION.

Dr. Bontecou asked if the same results could not be obtained by incisions into the deep fascia? If the pressure can be relieved by slitting open these structures which cause compression, will not the same results be obtained without the risk of secondary hemorrhage?

Dr. H. F. Campbell did not think that this would give relief, for the compression was not from simple swelling of the limb, but every muscle and every fibre of the muscle is distended.

Dr. Bontecou reported a case in which a man was brought into the hospital with his limb covered with blebs. He intended to amputate, but finding that the condition was the result of effusion, he made free incisions, and the man got well.

A paper, entitled

Impacted Intra-capsular Fracture of the Neck of the Femur—Bony Union,

being a description of a case by Dr. Senn, of Milwaukee, was read by the Secretary.

March, 1880. A lady, 75 years old, had fallen on the sidewalk, striking the left hip. On admission to the hospital there was slight swelling about the hip. The left foot was everted; accurate measurement showed shortening of one-third of an inch. On rotation of the limb the arc of the circle described by the trochanter major was greatly diminished. No crepitation could be elicited, nor could the limb be brought to its normal length. The diagnosis was impacted intra-capsular fracture of the neck of the femur, and the patient was placed in the recumbent position, and the limb supported on each side with sand bags. This treatment was continued for nearly three months. She was then placed on crutches. After the third week the shortening gradually increased, until it reached an inch. At the end of a year she could walk well by the use of a cane.

She was again admitted in February, 1882, suffering from catarrhal pneumonia, from which she died.

At the autopsy, the capsule, and especially the upper portion, was thickened and firm, and bridges of connective tissue connected the line of fracture with the anterior portion of the ligament. The line of fracture did not extend beyond the insertion of the capsular ligament. The line of fracture presented a serrated appearance. Longitudinal sections revealed a white

line of dense, compact bone. This was confirmed by the microscope.

The specimen from this case was presented to the Association for examination.

Dr. Moses Gunn, Ill., had examined the specimen, and thought that he traced the line of fracture running up outside of the capsular ligament. He thought that the head of the bone had received its blood supply in this way.

Prof. S. D. Gross had never seen bony union after intra-capsular fracture of the neck of the femur, and never expected to see it.

Dr. Moses Gunn, Dr. H. F. Campbell, Dr. Bontecou, and Dr. W. T. Briggs expressed the same opinion.

Dr. J. Ewing Mears, Phila., presented the results of some experiments he had made in connection with Dr. Morris Longstreth, Pathologist of the Pennsylvania Hospital, on the

Intra-peritoneal Method of Treating the Pedicle by the Ligature, after Ovariotomy.

He first described the various intra and extra-peritoneal methods of treating the pedicle, and then described the first experiment, which consisted in removing both ovaries of a rabbit, and on one side tying the pedicle with catgut, treated by the ordinary process, and on the other with catgut which had been submitted to a solution of chromic acid (1 to 5) for three weeks. Particular stress was laid on the fact that the ligatures were drawn only tight enough to control hemorrhage, and not tight enough to prevent the circulation in the smaller vessels. The rabbit was killed at the end of two weeks, and both ligatures were covered with lymph, a bridge of lymph extending across the groove made by the ligature and uniting the proximal and distal extremities of the pedicle. The raw surface had on one side been covered with lymph, and on the other was adherent to the broad ligament. The distal portion had been nourished in two ways, first by the bridge of lymph and second by interstitial nutrition.

The second experiment consisted in the application on one side of a silk ligature, and on the other of a linen ligature. These had been soaked in a solution of carbolic acid (1 to 20). The animal was killed after four weeks; the ligaments were covered with lymph and were beginning to disintegrate, and between the meshes of the thread wandering cells were found, indicating the manner in which the ligatures disappeared. He thought that two experiments proved nothing, but they might be taken for what they are worth. He and Dr. Longstreth expected to continue the experiments and report at the next meeting.

Dr. Mears presented for examination the specimens showing the results of the experiments.

Dr. Wm. A. Byrd, Ill., had had an opportunity of examining the ligatures after an ovariotomy, and had found them in the condition described by Dr. Mears. He, however, thought better results would be obtained by tension than by leaving a foreign body in the peritoneal cavity.

Dr. Moses Gunn, Ill., thought that if it were proven that nature would cause the absorption of vegetable as well as animal ligatures, it would be something decidedly new.

Dr. J. Ewing Mears had had an opportunity of examining the catgut ligature daily in an ovariotomy in which ligatures were applied, but where the clamp was subsequently required. At the expiration of two weeks the ligature had become a gelatinous soft mass.

After voting resolutions of thanks to the surgeons of Philadelphia, for their hospitality, and to the Commitee of Arrangements, for the efficiency with which they had carried out their work, the Association adjourned, to meet next year in Cincinnati, Ohio.

American Medical Association.

The twenty-third session of the American Medical Association convened at St. Paul, Minnesota, on Tuesday, June 6th, with an attendance of over seven hundred delegates and permanent members from all parts of the country.

After prayer, the Permanent Secretary read protests from most of the societies, against the admission of the delegates of the New York State Society, on account of their action in regard to consultation of regular practitioners with homœopaths. The protests were received by members with loud applause. They were referred to the Judicial Council, for action.

Letters of regret from Dr. S. D. Gross, of Philadelphia, and Dr. J. J. Woodward, U. S. A., of Washington, were read.

Dr. P. O. Hooper, of Little Rock, Ark., was then introduced as acting President, and read the annual address, in which he treated of the progress which had been made within the last year in all branches of science, and particularly in medical science. He also dwelt upon the importance of preventing the introduction into communities of contagious diseases, and stated it as his opinion that vaccination should be compulsory in all the States of the Union. He directed attention to the position taken by the New York State Medical Society, which endangered the very foundation of the Code of Medical Ethics, and stated that, as the matter was referred to the Judicial Council, whose decision would be final, he would refrain from saying further. In conclusion, he paid tribute to the President of last year, Dr. J. T. Hodgen, who died recently, at St. Louis, and to the President, Dr. J. J. Woodward, who is in Europe to regain his health.

It was decided to send a message of greeting to Dr. Woodward, by cable. A list of delegates was then read by the Permanent Secretary, after which the Minnesota State Society, in session at St. Paul, were invited to attend the sessions as members by invitation.

A communication from the Woman's National Christian Temperance Union was then read by Dr. N. S. Davis, of Chicago, in which they advocated introducing the study of physiology, anatomy, hygiene, and especially the results of the use of intoxicating liquor upon the human body, as a part of hygiene, in schools supported by public money. This was referred to the section on State Medicine.

The morning session then adjourned, and the delegates of the different States met separately to elect their member in the Nominating Committee.

The Pennsylvania delegation chose Dr. Fricke, of Philadelphia, as their representative, and instructed him to give his vote for the nomination of Dr. Atlee, of Lancaster, for the Presidency.

In a future issue we will give a detailed account of the proceedings.

The Medical Education of the African Race.

At a meeting of medical teachers and practitioners, called to confer with J. Berrien Lindsley, M.D., LL.D., of Tenn., in regard to the interests of a medical college for colored students, at Nashville, and held at the Hall of the College of Physicians, of Philadelphia, May 8th, 1882, Prof. S. D. Gross was invited to the chair and Dr. J. G. Richardson directed to act as Secretary.

Dr. Lindsley, at the request of the chairman, stated that the Congregational, Baptist, and Methodist churches of the North generously maintained, in the late slave States, about twenty-four institutions of learning for the benefit of the colored people, at an annual expense of nearly $300,000. Among these institutions were three medical colleges, one at Washington, one at Raleigh, and one at Nashville. The last of these, the Meharry medical department of central Tennessee College, had buildings costing $20,000, and was, in his opinion, decidedly the most favorably located.

His object was to gain the endorsement of representative physicians in the North, for the plan of creating a National Board of Trusts, chartered by Congress, for the medical education of colored people, which should be empowered to promote this most desirable object, by aiding the most promising educational establishment of the kind in the South, and further defraying the necessary expenses of those young persons of African descent who should display superior intellectual capacity, in Northern or European schools, as might best serve the great end in view, the elevation of the negro race. It being further designed that special attention should be paid to the complete preparation of colored physicians as missionaries and explorers in Africa.

Dr. H. Hartshorne highly approved of the proposed plan as explained by Dr. Lindsley, and only feared that unless the great advantages of his scheme were very fully understood, it would be difficult to induce all the various denominations interested in this missionary work to thus unite together for its successful prosecution.

Dr. Edward Hartshorne considered Nashville a great intellectual missionary centre, and that if we could establish a good medical school there, the best colored men from the whole Southwest would flock to it, and from these the selected few who developed in advance of their race could be sent, on this well devised plan, to Northern colleges, where the best possible medical training could be secured for them.

Dr. L. D. Harlow remarked that he had been very much interested in this admirable project of Dr. Lindsley's, and was ready to endorse all that he had planned for the elevation of the black people. He sincerely hoped there would be no difficulty in procuring the requisite charter from our national legislature.

Prof. James Tyson observed that his study of the important subject of medical education had rendered him opposed to the erection of any new colleges, but he did not entertain the same objection to fostering an already established Institution. For the last four years colored students had matriculated at the University of Pennsylvania, and one of these graduated the past year with an average as high as that of three-fourths of the class. Another, who will probably graduate next year, has already passed in Chemistry, with the unusual average of 98 in a possible 100. Only one white student is even reported to have left on account of the admission of these colored men, so that the question is practically settled in regard to the University of Pennsylvania, as it is also in the affirmative, in Harvard University.

Dr. J. Cheston Morris believed that, having lived, formerly, on a plantation in one of the Southern States, he was intimately acquainted with the black man's capacities, and he was satisfied that for the next 20, 40, or perhaps 100 years, but a small proportion of the negroes could acquire the preliminary training necessary for a great physician; until that time, he was convinced that the wisest plan would be to maintain a good medical college in the South, at some central point like Nashville.

Dr. J. Solis Cohen called attention to the fact that in seven years the Meharry school had graduated only 23 students, and urged the advantages of combining the three southern colleges into one strong institution, as soon as possible.

The Chairman, Prof. Gross remarked, that if the negro race could develop a great physician in a hundred years, it would prove its vast superiority to the whites, who had required some two thousand years to accomplish the same feat. He believed that the blacks had capacities which in time will develop to a very high degree, but for the present the negro must have his own schools. Applicants had always been refused at the Jefferson Medical College, and it would probably be a long time before they gained admittance, if they ever did so; he, therefore, cordially approved of the plan of Dr. Lindsley.

Dr. Lindsley said he knew, from his own personal observation as former Health Officer of Nashville, that there were in that city hundreds of colored people suffering for want of proper medical care. This state of things, lamentable as it was, existed generally throughout the South, because white physicians could not attend the blacks out of charity, to the extent they used to do, when amply recompensed for their services by the owners of these former slaves. It was to provide qualified medical attendants from their own people, for these suffering human beings, that he invoked the influence of the 70,000 physicians of America, and the substantial aid of the benevolent public at the North.

Dr. J. G. Richardson suggested that the question now before the meeting was not so much how far the black man could be medically educated? but whether this great experiment, which will certainly be tried, shall be attempted under the most favorable circumstances as contemplated by Dr. Lindsley's plan, or whether the pecuniary

advantages which contributions from Northern philanthropists would procure, shall be frittered away in the incomplete support, of six or eight feeble medical colleges? He, therefore, moved that a committee of three be appointed by the chair, to prepare a suitable endorsement of the proposed National Board of Trusts, for the medical education of the colored race.

Dr. Edward Hartshorne moved that the committee be authorized to add to its number, and invested with power to act for the meeting; which resolution and amendment were carried unanimously, and Drs. H. Hartshorne, Richardson and Harlow appointed on the committee.

On motion adjourned.

JOS. G. RICHARDSON, *Secretary.*

The Code of Ethics.

At the late meeting of the Southern Illinois Medical Association, held at Carbondale, Ill., May 17th and 18th, 1882, on motion, a committee was appointed to draft resolutions expressing the sense of the Association in relation to the existing Code of Ethics, which committee presented the following report, which was adopted:—

"The committee to which was referred the preparation of resolutions expressive of the sense of this Association relative to the Code of Ethics, beg leave to report as follows:—

Resolved, That the Southern Illinois Medical Association regard the Code of Ethics of the American Medical Association as eminently just, being founded on truth and sound principles, and that although we wish to be liberal in attaining that end, we should not lower our standard, or trail it in the dust; but firmly defend the right.

Resolved, That a copy of these resolutions be transmitted to the Secretary of the American Medical Association, and that our delegates to that body be instructed to use their votes and influence to retain the existing code."

On motion, the Secretary was instructed to send a copy of the resolutions to a few representative journals, for publication.

H. R. Guthrie, M.D., L. H. Spencer, M.D., S. W. Marshall, M.D., Committee.

JAMES I. HALE, M.D., *Secretary.*

The Gross Professorship of Pathological Anatomy.

A special meeting of the Alumni Association of the Jefferson Medical College was held May 30th, to take action looking toward the endowment of a Professorship in the College in honor of Professor Gross.

Dr. Addinell Hewson was called to the chair and Dr. R. J. Dunglison presented the report of a committee which had been appointed to consider the subject. The Committee recommended the adoption of the following resolutions:—

Resolved, That in appreciation of the great services of Professor Samuel D. Gross to medical teaching in this country, a memorial professorship of Pathological Anatomy be founded by this Association, to be known by his name.

Resolved, That a permanent committee of five be appointed, with power to increase it to a number not exceeding nine.

Resolved, That an Auxiliary Committee be appointed by the Permanent Committee, subject to the approval of the Executive Committee, from the non-resident Alumni.

Resolved, That all vacancies in either committee, shall be filled by the Permanent Committee, subject to the approval of the President.

Resolved, That the Executive Committee shall appoint as trustees of the fund for the professorship, a reliable trust company in the city of Philadelphia.

Resolved, That when, in the opinion of the committee appointed by the Executive Committee of the Alumni Association, the sum be sufficient, a professorship be endowed, on such terms as will best attain the objects proposed by these resolutions, by a sub-committee, of equal numbers of the Executive Committee and the Trustees of Jefferson Medical College.

With the exception of the fifth resolution, which relates to the Trustees, and which was referred to the Executive Committee with power to act, the resolutions were adopted.

The committee also reported that the sum of $2000 was promised by an Alumnus at a late meeting of the Executive Committee, as soon as the fund should reach $8000.

The committees referred to in the resolutions will be appointed by the chairman, hereafter.

The Tenth German Medical Congress

will open in Berlin, June 30th, and close July 2d. The following subjects will mainly be debated: 1. Civic regulations for physicians. 2. Feeding of infants. 3 Necessity of prolonging medical studies to five years. 4. Exhibition for hygiene and of measures etc., in cases of accident. The latter affair will have to be dropped, as the building of the exhibition and a great deal of material which had been stored already in the building were destroyed by fire, May 12th. The loss is said to reach a million dollars.

Dr. Gray.

At a recent meeting of the Medico-Psychological Association of England, the president referred to the attempted assassination of Dr. Gray, of the Utica Asylum, and a resolution of sympathy was unanimously adopted.

QUERIES AND REPLIES.

Subscriber, Mich.—Dr. John J. Reese, Professor of Toxicology in the University of Pennsylvania, says that he has never heard of any toxic effects from oxalate of cerium. Spts. of nitrous ether would, no doubt, in excessive doses, produce much the same poisonous effects as sulphuric ether.

DEATHS.

SEARY.—On May 8th, Charles W. Seary, M.D., in the 39th year of his age.

TROMPETER.—Dr. G. Trompeter, a physician of Port Chester, West Chester Co., N. Y., while hurrying to catch a train at that station, late on Friday afternoon, May 5th, fell dead as he reached the platform. The cause of his death was heart disease. He was 32 years of age, and single. He had resided at Port Chester only 10 months.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

EPIDEMIC DYSENTERY,

AS IT MANIFESTED ITSELF IN TRENTON AND A PORTION OF GIBSON COUNTY, TENN., IN THE FALL OF 1881. ITS HISTORY AND ETIOLOGY.

BY T. J. HAPPEL, M.D.

Read before the Medical Society of Tennessee, April 10th, 1882.

Gentlemen:—Without any useless waste of words, or consumption of time, in defining dysentery, or entering into any explanation of the terms sporadic and epidemic dysentery, I propose giving you a short history of the epidemic of dysentery which prevailed in Trenton and its vicinity during the fall of 1881.

I desire, in the first place, to call your attention to a few cases occurring in my own practice, and then to others of which I have reliable and trustworthy information.

My first case occurred September 13th, 1881, in the person of a negro woman, advanced to within a few days of the full term of pregnancy.

Occurring thus late in pregnancy, it could readily be accounted for—having been due, no doubt, as the immediate or exciting cause, to imprudence in diet, producing a diarrhœa, which, in the congested and turgid condition of all the pelvic viscera and blood vessels, was easily converted into an inflammatory condition of the lining membrane of the rectum.

The dysenteric discharges continued for three days after delivery, supplanting to a marked extent the lochial discharge.

Treatment by saline purgatives, followed by opiates, in this case availed but little, except to relieve the tormina and tenesmus, both before and after delivery. Finding no cure in such measures, I resorted to the following:—

℞. Pulv. ipecac co., ℈j
Pulv. ipecac, ℈iv. M.
Ft. cht. No. iv.

Sig.—One after each action till relieved.

In forty eight hours the case was virtually cured. The lochia then began to increase, and the patient rapidly convalesced.

My second severe case occurred in our city, in the person of a stout, vigorous, colored, blacksmith. This case we will style No. 1, in a series of fatal cases to follow.

The patient in this case was addicted to what would be called by whisky drinkers the temperate use of whisky, viz: the using as much as from three to ten drinks per day, or as much as one can conveniently take and not be unfitted for work or business thereby. This daily use of stimulants had lasted for years.

So far as I could reliably ascertain, the first dysenteric symptoms manifested themselves Monday, October 3d, a raw, damp, rainy day. Being busy at his shop, in spite of the weather and his disease, he worked at his forge and shoeing horses, stopping about every thirty minutes for his bowels to move, complaining constantly of much abdominal pain. He returned to his forge on the next day, but was advised to go home, keep quiet in bed, take a mild saline cathartic and follow its action with an opiate. Late in the evening he did so, after exposing himself all day, in and out of the shop, alternately heated by the forge and chilled by the cold rain still falling at intervals.

On the 6th inst. I was called to see him, and continued visiting him from that time to the day of his death, October 16th.

In this case every plan of treatment was persevered in until it was found to be of no avail.

About October 11th the actions became sero sanguinolent and extremely offensive. Adynamic symptoms were rapidly developed and the patient steadily sank.

In addition to the remedies used in ordinary cases quinine was administered freely, about 30 grs. daily.

The residence of this patient was far better than that of the generality of the colored race, but its location was in the lowest portion of the city, within three-quarters of a mile from the river, on the east, with its malarial surroundings.

Case No. 2 of this fatal series occurred October 12th, in a family south of our city, in which there had been a death from dysentery a week before.

That case was treated, in my absence, by another physician. Reference will be hereafter made to this case.

The patient referred to as Case No. 2 was a bright boy, white, aged about five years. He, with two others, had been attacked, a few days after the death of the case already referred to, with well marked symptoms of acute dysentery, and all had been treated by the father and mother with saline purgatives, followed by laudanum, and, as the family thought, successfully, but after a subsidence of the symptoms in all the cases, the disease returned, with renewed and redoubled vigor, in this one.

I was called to the patient October 15th, the day following this relapse.

There were present the characteristic mucous, bloody discharges, small in quantity, accompanied with pain, etc. In some of the motions mucus predominated, in others blood. Occasionally fecal matter was discharged with the mucus and blood. Tongue heavily coated, dark yellow and dry. Pulse good, 96. Temperature 101°, but reported to have been very high on the night of the 14th, about midnight, before I was called. Much nausea and frequent vomiting.

Administered morphia sulph. to quiet pain and vomiting. Directed hot mustard cataplasms over the abdomen, to be renewed every two hours, and prescribed as follows:—

℞.	Hydrarg. chlor. mit.,	gr. iij
	Santonine,	gr. iv
	Pulv. ipecac co.,	gr. vj. M.
	Div. cht. No. iij.	

Sig.—One every three hours, followed by oil, if needed, to produce fecal discharges; and

℞.	Quiniæ sulph.,	ʒ ss.
	Doses No. x.	

Sig.—One every two hours till six were given, then at intervals of four hours.

And in addition to the above a febrifuge mixture, to be used pro re nata.

At my visit the following morning I found that, with the aid of oil, several large lumbrici had been expelled, and that although some mucus was being passed, it was much reduced in quantity.

Prognosis more hopeful.

Prescribed tr. opii; continued the quinia and febrifuge mixture as before, and directed that in case of a return of the dysenteric actions, a saline purgative be administered, followed by an opiate.

At my third visit, made twenty-four hours later, I learned, from the family, that in a very short time after my previous visit the mucous, bloody evacuations reappeared, becoming shreddy, and with much more pain; and that after administering the saline purgative, as directed, a fecal discharge had been obtained, to be followed, at once, by larger mucous, bloody ones, with increased tormina and tenesmus. I then resorted to larger doses of pulv. ipecac, but to no avail. The pain and suffering of the patient continued to increase, and could be allayed with large doses of morphiæ sulph. only. Early in the morning of October 18th the patient died. No post-mortem.

Case 3 in this series has been already referred to under Case 2, as belonging to my practice, but having in my absence fallen into the hands of another physician, who was, by the family, continued in the case. This case occurred October 7th, and terminated fatally October 10th.

From the family I learn that at the onset of the attack, true, acute, dysenteric symptoms were presented, followed by larger, dark discharges, and collapse; though the death appears on the records as one of cholera infantum.

Cases 2 and 3, as already stated, occurred in the same house, and, had they been sporadic cases, would have been easily accounted for by malarial surroundings as the predisposing cause, and drinking water as the exciting one.

The water used by the family was, mostly, from a cistern that had not been cleaned for several years.

Case 4, of this fatal series, did not occur in my practice, and was in an entirely different portion of our city from Case 2, being on one of its highest points. The patient was a man advanced in years, and, up to a very few years ago, a very

free user of whisky, keeping much under its influence the greater portion of the time, though lately he had not used it so freely.

About three years ago symptoms of cerebral softening appeared, but made slow progress. In this case there had been for some time a torpid, semi-paralyzed condition of the rectum and descending colon.

From the "Records of Births, Deaths and Marriages," I glean the following, in the same series.

Case 5, a white male, aged seven years, occurred inside the city limits, in a portion of our city noted for its healthfulness. The lad was stout and vigorous, rarely ever known to be sick. After an illness of ten days he died, October 22d.

Case 6, an infant, 18 months old, in the neighborhood south of our city—about four miles distant, and about a mile south of Nos. 2 and 3—died September 1st.

Case 7, a white female, aged six years; died September 25th, not far from No. 6.

From reliable sources I collect three more fatal cases, viz:—

Case 8, adult female, the mother of No 7, mentioned above, died October 1st.

Case 9, a colored child in the same neighborhood, and not far distant from No. 6, died October 10th.

Case 10, in a different portion of the district, was a child nearly two years old, in whom the disease became chronic after an acute attack, the death occurring late in November, the child having been sick several weeks.

These ten fatal cases were in district No. 7, in which our city is located.

From Dr. Moore, living northeast of us, in district No. 11, I get information to the following effect:—

He gave prescriptions, at his office, to a considerable number of applicants, presenting dysenteric symptoms, and, excluding these cases of office practice, he visited and treated twenty-six case of dysentery during a space of time dating from September 15th to November 1st, by far the larger number of his cases occurring from October 1st to 20th. Of these twenty-six cases five proved fatal.

Continuing the number of the fatal case series, from Dr. Moore's cases we get—

Case 11, a colored male, adult.

Case 12, an adult female, white, two months advanced in pregnancy.

Case 13, a child, aged 4 months, white.

Case 14, an adult female, white.

Case 15, a child, aged two years, white. These all died between October 1st and 20th. All of these last mentioned fatal cases, except one, were in poor circumstances, and could not and did not have much needed attention and nourishment.

There occurred in Dr. M's practice, among the twenty-six cases spoken of, one in a woman, pregnant eight months, that recovered.

The treatment was varied to suit individual cases. In some particular neighborhoods, in his scope of practice, cases were much more numerous than in others, and more difficult to treat.

From Dr. Bright, in District No. 5, southwest of our city, I learn a state of facts very similar to the above.

Now, having followed the scriptural example, of presenting the bad wine first, I return to a consideration of the disease as it occurred in our city and district, not claiming to take up in the order of occurrence, but according to importance, etc.

One of the first cases in our city was in the person of an adult female, pregnant seven and one-half months. The family was in straitened circumstances, noted for imprudence, and she had the care of an invalid husband in addition to other maternal duties. Under treatment for a few days, she recovered, with no tendency to abort.

Later in the epidemic, I find in the records of my own practice a case of dysentery in a female, pregnant between one and two months. This case recovered without any serious trouble, after several relapses.

In the same family in which Case 10 died, another very serious case occurred, of about nine days' duration.

Almost in the same neighborhood were three other very serious cases; two children between four and seven years of age, and one adult female.

In October, in the practice of Dr. C., was also a severe case in an adult male aged 50 years. Resulted favorably.

From October 1st numerous cases (mild as a rule) occurred simultaneously, in and around Trenton, among parties who had never been in contact with each other. The universal complaint with all who were sick was enteric trouble, and in four-fifths of these cases dysenteric symptoms were reported. The epidemic was at its worst during the twenty days from Oct. 4th to 23d, inclusive.

The "Gibson County A. and M. Association" held its annual meeting from October 11th to 15th, inclusive, and many attended the fair, exposing themselves, in so doing, to the rays of

almost a midsummer's sun. On Thursday, October 13th, nearly 5000 people were present, including 2500 children. On Friday 1500, and on Saturday 2000, or more. These days were exceptionally hot, dry and dusty, and those attending either brought their dinners, or ate barbecued dinners, served on the ground. Many families in our city suffered, and throughout some of the adjoining districts, the week following the fair was one of sickness from dysenteric troubles.

In my own family, one-half, myself in the number, was sick, three out of six, all adults.

The cases were mostly of a mild type, yielding to treatment, so far as the acute symptoms were concerned, in 24 hours, but disorders of digestion continued from one to two weeks, with enteric irritation, in many cases. In a large number of cases the mildest diet and the most easily digested substances were required to prevent a relapse; yet mild relapses were frequent—often relieved by proper and guarded eating.

The different methods of treatment seemed equally successful. A few of the cases, as already stated, were disposed to be chronic, but after from one to two weeks' suffering, with the advent of settled cool weather, slowly recovered.

My estimate of the number affected, including mild cases, is that at least 15 per cent. of the population of our city, and that portion of the district south of us suffered. Dr. Moore does not think the percentage quite so great in his territory, but Dr. Bright makes about the same estimate, so far as his knowledge of the disease extends.

Now, whence came this epidemic? What is, or was, its etiology?

Any one accepting the generally believed doctrine of that Pandora's box of disease causes (and but few deny its all-powerful influence), who will read Dr. Waterfield's description of the sanitary surroundings of the City of Trenton, and its vicinity, as set forth in his report to the "State Board of Health" in 1879, will at once conclude that the chief, if not sole, factor in producing the epidemic was *Malaria*. I seriously doubt the correctness of the assertion made in some of our text books, that the epidemic form of dysentery is due chiefly, if not solely, to malarial influence.

No epidemic of dysentery has occurred here for years.

In 1874 and 1875, when intermittent and remittent fevers prevailed to an alarming extent, so much so that in some neighborhoods in this county there were not enough well persons to nurse the sick, scarcely a case of dysentery occurred.

From that time till now only a few sporadic cases of the disease have each year occurred, while there was during that period of time (six years) a continued decrease of intermittent and remittent fevers, till this year, which has shown a minimum of true malarial fevers.

If malaria had been the chief exciting cause, then we should have had no dysentery this year, while it has been at its maxinum.

Malarial influences alone, then, will not account for the epidemic, as even the chief factor in it, for, as has already been stated, this portion of our county has been, this year, remarkably exempt from the different forms of intermittent and remittent fevers, generally; and, no doubt correctly, attributed to that unknown and undiscoverable something—malaria.

(*To be Continued.*)

CHOREA.

BY DR. R. B. GLASGOW.

Read before the Northern Medical Association of Philadelphia.

Mr. President and Gentlemen—I desire at this time to invite your attention briefly to those incoördinate and involuntary contractions of the voluntary muscles ordinarily described by medical writers under the title of chorea, and which are known by non-medical people as St. Vitus dance, St. Anthony's dance, and the Devil's dance, or the jerks. This last, though it is a very vulgar name, expresses well one of the most prominent symptoms of the disorder.

A host of medical observers have made this disease the object of careful study, and the observations recorded by these gentlemen form a very voluminous literature, to become conversant with which one may refer with profit to the works of Ziemssen, Charcot, Romberg, Rosenthal, Watson, Landon Carter Gray, Weir Mitchell, and to the clinical notes of forty cases of chorea, published in the Philadelphia *Medical Times*, March 27th, 1875, by our friend and neighbor, Dr. Charles K. Mills, to whose honesty and accuracy as an observer I gladly bear witness.

In my studies I have been very much impressed with the diversity of the statements of different individuals who are recognized authorities on the subject, and in my remarks at this time, I will direct your attention mainly to those points on which the authorities differ most widely. Some writers describe the disorder under two forms, viz., chorea major and chorea minor. To me, this appears an unnecessary

labor, the difference between the two being a difference in degree only.

The causes of chorea naturally divide themselves into predisposing and exciting. These I will not attempt to enumerate, lest you tire. In passing, it may, however, be said, that nearly every known abnormal condition, from a sclerosed cerebral cortex to an elongated prepuce, have at various times been considered influential in the causation of the disorder.

We may, I think, regard it a certainty that females are much more liable to the disorder than males. The period of life between the second dentition and puberty, and in this latitude the late winter and spring months, seem especially favorable periods for the development of chorea. The influence of rheumatism and cardiac affections in the production of chorea is a mooted point. Please observe carefully the following reference, which may already be familiar to some of you: "The relations of chorea to rheumatism have been recognized since the beginning of this century. The appearance of cardiac bruits during this disorder was noticed by Addison, and at a later period, by Todd. Romberg and Grisolle considered rheumatism and cardiac affections as mere accidental complications of chorea. But Watson demonstrated, by an analysis of 309 cases observed by Hughes, and 36 cases by Kirkes, that in twelve fatal cases the heart was found diseased ten times, and that among 104 carefully observed cases only fifteen were free from cardiac bruits or rheumatism. Among 128 children affected with chorea, observed by Sée in the Children's Hospital of Paris, there were 64 cases of rheumatism, a fact which is so much the more important because rheumatism, as we all know, is very infrequent among children. Senhouse, Heslop, and Roger have endeavored clinically to establish the relations existing between chorea, rheumatism, pericarditis and endocarditis, holding that both affections are the common expression of one and the same pathological condition. According to observations made at Prague, by Steiner, this pathological relation does not possess an absolute value, since among 254 cases of chorea only four appeared during the course of acute articular rheumatism. It is, therefore, probable that under the influence of local causes the coincidence of the two diseases is observed much more frequently in certain countries, and that certain conditions render the action of the rheumatic inflammation upon the serous membranes, the articulations, the spinal meninges, and the centres of coördination, more frequent and intense. Hughes and Trousseau have observed chorea more frequently after scarlatina; according to Levick, chorea is observed much more frequently among the lower than among the better classes of the population." My own belief is that children of rheumatic or phthisical parents are especially liable to chorea, and I am inclined to believe that any circumstance that impairs the vital powers of the adolescent predisposes to chorea. Fothergill describes the lower classes of the population of large towns as being "ill fed, ill bred, the degenerated products of poverty, lust and syphilis, reared on tea, with a dash of alcohol," a combination of circumstances, I think, eminently fitted to predispose to chorea.

The rôle which anæmia, chlorosis, constipation and intestinal irritation play in exciting an outbreak of chorea, is sufficiently well known to need no discussion here. The symptoms of chorea have no regular course of appearance. Now coming suddenly, following hard on a fright or some shock to the nervous system. At other times coming on gradually, having for prodromata, headache, pain in the cervical and dorsal regions of spine, malaise and changed mental conditions, dullness being probably more frequently observed than otherwise. Not infrequently the patient is scolded for being mischievous, or is thought to be becoming paralyzed. Pain on pressure in the cervical region of the spine is stated, by Bartholow, to be a constant occurrence. This statement I am inclined to disallow. The influence of the patient's will over the movements is variously stated. Cases have come under my notice, in which the more the patient tried to control the movements the more violent they became. The subsidence of the twitching during sleep is recorded by some observers as being constantly noticed. Marshall Hall has, however, observed the persistence of this symptom during sleep in which the patient dreams. One case is recorded in the clinic for nervous diseases at the Hospital of the University of Pennsylvania, in which a relapse of the symptoms came on during sleep in which the patient, who lived near the University, dreamed that she was being "cut up" by medical students.

One case came under my notice, who did not speak a single word for a whole week, presumably on account of the choreic movements of the tongue rendering articulation impossible. The symptoms of chorea, considered in the aggregate, form a picture not easily forgotten. The number of muscles involved and the intensity of the contractions produce great diversity in the symp-

toms, and have doubtless given rise to such terms as hemichorea, local chorea, etc. I have never seen a case of chorea major, described by some writers, but I fancy, from the descriptions given of it, that there may be some likeness, in the movements of one so afflicted, to the movement of a chicken that has had its head suddenly lopped off. The duration of chorea is variously stated at from three weeks to as many months, and it usually terminates in recovery; the probability of this termination is, however, lessened by cardiac complications; hysteria is a not infrequent term of chorea. Relapses of the choreic movements not infrequently occur.

The diversities of opinion as to the pathology of chorea are mostly between the older writers and those who have studied the matter more recently, with the aid of the microscope. Still, some modern authorities, among whom may be mentioned DaCosta, hold that chorea is essentially a functional disorder of the nervous system. See fourth edition "DaCosta's Medical Diagnosis.

This agrees well with the statement by Watson, that "the complaint in its genuine form is seldom dependent on any organic or inflammatory change. The instrument, he says, referring to the nervous system, "is not broken anywhere; it is simply slackened, jangling, and out of tune." See "Watson's Practice of Physic." These statements most certainly do apply well to those cases of chorea which recover promptly and perfectly.

Meynert demonstrated microscopical changes of a degenerative nature in the cells of the cerebral cortex.

Broadbent, Tukewell, Hughlings Jackson, and others, have called attention to the presence of minute capillary emboli in the corpus striatum and optic thalamus. My own disposition is to regard chorea as the expression of a group of diverse pathological conditions, for the division of which into separate clinical entities we must wait upon the pathology of the future. The rarity of a fatal termination of a case of chorea has doubtless an unsettling influence upon the views of pathologists in the matter. Rosenthal states that "the chorea which is manifested in articular rheumatism, in inflammation of the pericardium or endocardium, in affections of the female sexual organs, in intestinal irritations, is of reflex origin, and is due to a congenital exaggeration of the excitability of the apparatus of coördination, the latter being disturbed in its functions by the period of puberty, by psychical excitement, and by constitutional debility."

In forming your judgment as to the probabilities of the recovery of a case of chorea, be guided by the following circumstances, viz.: The existence of protracted sleeplessness, cardiac involvement, and pregnancy. The first named of these conditions will wear your patient out; from the cardiac trouble he will probably never recover; and in pregnant women the chorea will not cease, likely, till after delivery. The other cases will probably terminate in recovery spontaneously, or by treatment, as is well described by a prominent authority on the subject, as follows: "The morbid disposition which gives rise to the disorders of coördination may disappear spontaneously, as the organism of the young patient becomes more vigorous, or it may yield to the remedies employed to restore the energy of the nervous system. Sometimes you will find recent cases of chorea arrested by the development of intercurrent diseases, viz., the acute exanthemata." The diagnosis of chorea is said to be usually easy, but there are cases in which I fancy it would not be easy to say where the chorea left off or where the hysteria began. The near relation of chorea to hysteria is pointed out by Rosenthal, Charcot, and by Landon Carter Gray, in the *Archives of Medicine* for October, 1879. Incoördination is the diagnostic symptom of chorea; this symptom is also observed in paralysis agitans, which, however is a disease of patients of more advanced age than is common for choreics. The loss of power in choreic patients may at times puzzle you. A mother brings to you her child, with the statement that the child must be losing the use of its hands; it is constantly letting objects fall. Just ask the child to perform some trifling voluntary act, and the nature of the case will most likely become plain at once. Let us now consider briefly the treatment of chorea. An enumeration of the remedies which at various times have been thought useful in the treatment of chorea, would not only be tedious, but useless. From Guy's Hospital, London, the report comes that by rest in bed in a quiet, darkened room, with proper alimentation, the disease has a spontaneous tendency to recovery in two or three weeks. This treatment, which is probably as rational as any that can be mentioned, is, I should think, especially useful for those cases in which the heart is complicated, but is capable of application in private practice in a limited number of cases only. To prescribe rationally for a disorder the essential nature of which we are in doubt of, is manifestly impossible. That any remedy will be found whose action on chorea will be analogous to the action of

quinia on ague, or of mercury on syphilis, is quite improbable.

The arsenic treatment of chorea has the advantage of being economical and easily administered; very desirable points. Recently, at the clinic for nervous diseases at the University Hospital, the arsenic treatment has been reinforced by the addition of quinia to the treatment, and though the observations in the matter are not sufficiently numerous to warrant a definite statement as to the value of this agent, yet the results appear to warrant an extended trial of the remedy. In treating a case of chorea see that the patient gets light suppers, which may be followed in the evening by morphia and chloral hydrate, if necessary, to secure sleep. The exhibition of spigelia and senna, or the mild chloride of mercury, and santonin in the beginning of the treatment of a class of cases will do no harm, if it does no good. If the patient is a female, in whom the menstrual discharge is not properly established, the use of Mettaur's aperient, a solution of aloes, bicarbonate of soda and valerian, might be indicated.

If it should be desirable to exhibit the arsenic and quinia in combination, it may be accomplished by using the liquor arsenici chlor., acid hydrochloric, quinia sulph., infus. gent. co. syrup, and aqua, in one solution. If the remedies are used separately, Fowler's solution, as much as may be necessary to produce the physiological effects of the drug, and about six grains daily of the quinia, may be used. This is exhibited perhaps least unpleasantly in one dose, at bedtime, in a solution of equal parts of fluid extract of liquorice, simple syrup and water. These should not be mixed till just before they are taken. A maximum amount of sunlight, fresh air, good food, and tepid bathing, followed by frictions of the body with a rough towel, are useful adjuvants to the treatment. The immediate isolation of the choreic patient is a point worthy the notice of medical men who may have charge of institutions in which numbers of female children are grouped.

Hospital Reports.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

CLINIC OF FRANCIS DELAFIELD, M. D.,
Adjunct Professor of Pathology and Practice of Medicine.

Bright's Disease and Rheumatism.

GENTLEMEN:—This woman, thirty odd years old, complains of what she calls rheumatism, which has lasted three months, beginning as a pain and stiffness in one of the knee-joints, then extending to the other, and afterward extending still further and involving the joint of the finger, and affecting in some degree the neck and shoulder. It has not, however, become very severe in any of the joints, as she is still able to walk and to use her hands, although there is a certain amount of pain and tenderness.

Then, in addition, we find that she has suffered from dyspeptic symptoms, from occasional nausea and attacks of sick headache. Several years ago she had an attack of jaundice, and we find that three years ago there was œdema of the legs, lasting for several weeks, and at that time her physician said she had kidney disease. Since then she has been passing about two quarts of urine a day, and at present the urine contains a trace of albumen.

Now, it is evident that here we have a case which presents two distinct features, either of which might have occurred without the other, but here they are associated, as they not infrequently are, in the same person. This woman is suffering at the same time from chronic rheumatism and from chronic diffuse nephritis, and from that form of chronic diffuse nephritis, one can be tolerably sure, in which the kidneys become gradually atrophied, the atrophic form of chronic diffuse nephritis. [Patient sent out.]

The prognosis of either of these two conditions is bad enough, and when you have them associated together, of course, the prognosis is still worse, and for that reason I did not care to talk about the case before the patient herself. She is still in fair condition; her complexion is good, she does not look like a sick woman, and yet she has fairly begun with two conditions, each of which is likely to become worse and worse, and in each of which the symptoms will become more and more troublesome; yet we cannot tell how long a course either of these diseases will have. They may last a long while.

In the first place, with regard to the chronic rheumatism, having begun in one joint, and extended, involving others, the probabilities are that it will be a bad form; that which keeps getting worse and worse, involving different joints, and finally crippling the patient.

The form of chronic diffuse nephritis from which she is suffering is that which may go on a long while, developing few symptoms, but which at any time may develop very marked symptoms. The dyspeptic symptoms of which she has complained may at any time become worse, and her general nutrition be affected; she may grow anæmic, and instead of having good color, as at present, may lose the florid hue, and become pale; cerebral symptoms may develop at any time.

Then the question arises, what can we do for this woman? Here we are limited very much by her circumstances. She is evidently a person who has to earn her own living; she will have to remain where she is, and no very thorough treatment can be carried out. If she were a person in good circumstances she could be benefited to a certain extent by travel, by the use of natural mineral waters, especially the sulphur waters. These would be of service both for the kidney trouble and for the chronic rheumatism.

As the case stands, I suppose the best thing we can do for her will be to put her upon the use

of small doses of the bichloride of mercury, letting her take this for a considerable length of time. She should take a thirtieth of a grain of the bichloride of mercury in a bitter infusion, keeping it up for several months. Then, in addition to this, she may with advantage drink some of the alkaline waters, as the artificial Vichy water which is made in this city, a pint to a quart every day; that, I presume, is the best we can do for her under the circumstances, but I expect she will steadily get worse instead of getting better.

Aneurism of the External Iliac.

This man, fifty-two years of age, complains of a pain in the right groin and hip. It has been present more or less during two years past, but it has not been severe enough to keep him from his work until the past two weeks, during which it has been steadily growing worse. When the pain and soreness could be felt he noticed some swelling in the right groin; perhaps, he says, it was there in greater or less degree during the intervals as well, but his attention was not drawn to it except when the above symptoms were present.

On examination we can see at once that there is a lack of symmetry between the two groins; that the right is distinctly larger than the left. When I put my hand upon this tumor I feel a pulsation, and those of you who are near can see my hand moved with the pulsations. It has considerable firmness. It is about four inches in length and two and a half wide. I can get no murmur over it.

The case is evidently one which belongs to the surgical clinic rather than to the medical; a case of aneurism of the external iliac or of the femoral artery, really just about the bifurcation, where the artery passes over the brim of the pelvis. It has already reached considerable size, and the treatment is surgical rather than medical. The tumor, so far, seems to have caused him little inconvenience except pain, but as it has suddenly been becoming larger and larger, the pain has become more severe, and the man was driven to seek relief. He will be made more comfortable while the question is being agitated as to the best surgical treatment, simply by taking the iodide of potash, just as a man would with aneurism of the arch of the aorta. It will diminish the force of the heart's pulsation, it will probably make the tumor a little smaller and the pulsations less vigorous, and the man will be more comfortable.

Phthisis, with Complications.

This young lady was sent here as presenting a case of chlorosis. You observe that she is anæmic, but the anæmia is merely a symptom of the actual disease from which she is suffering. She, I think, has spoken quite right about her condition, that she has consumption. It began probably two years ago, at the time she mentioned. She also says that she is suffering from diarrhœa, which is persistent, and has lasted for a considerable length of time. I presume that this diarrhœa is associated with the condition of the lung, and that it is caused by the existence of ulcers in the small intestine; the kind of ulcers which occur as a regular complication of chronic pulmonary phthisis. We have found that there is dullness on the right side of the chest, and that there are subcrepitant râles in the same region. The amount of trouble which she has with the lung, so far as extent is concerned, is not very great, and yet the girl is run down very much indeed. She is very anæmic, and is made a great deal worse by this complication, chronic diarrhœa. I think it very probable, from her appearance, that she may, by this time, have very well developed a complicating kidney disease—chronic diffuse nephritis.

The best thing she could do would be to go into a hospital. She does not look as if she were well cared for. She wants to be where she can get enough to eat, and I think the immediate indication is, not to treat the local disease, but to treat the general state of the system, which is the result of that disease. I should treat her as if it were a case of chlorosis, simply putting her on the use of iron, combined with the inhalation of oxygen, without paying special attention to the lung trouble; and then in addition to this I should try to treat the chronic diarrhœa; and the first drug which I should use for this purpose would be one of the mineral acids, say the dilute hydrochloric acid, in doses of twenty drops four times a day; and to this I should add a very little opium, say three drops of laudanum with each dose, merely for the sake of checking the diarrhœa. Should she do this I think it very probable she would get a good deal better, perhaps enough better to be able to go on with her work again. That she would get permanently well, is not likely.

Miliary Tuberculosis.

We have here a man, thirty-seven years of age, who says he was well about sixteen months ago; that he was engaged about a slaughter house, at tolerably hard work. He then began to cough, and treated himself with domestic remedies, but the cough got worse instead of better, and it has continued ever since. It is accompanied with muco-purulent expectoration, which is sometimes streaked with a little blood. But he has never raised blood in any amount. The cough is now apparently a very troublesome feature of his case. It keeps him awake at night, and is sometimes so severe as to cause him to vomit his food.

Besides the cough, he has become very short of breath; he is troubled with palpitation of the heart; has lost his appetite; has become very emaciated; very anæmic; his bowels are constipated.

The man's condition at the present time is, as you see, very bad; he is very feeble; very short of breath; he might perhaps better be in bed than be here.

When we come to examine his chest, we find that the heart is increased in size, and that the character of this increase seems to be rather in the way of dilatation than of hypertrophy, but I find no evidence of valvular trouble. We find over the right lung good pulmonary resonance, exaggerated breathing, with prolonged expiration. Over the left lung there is slight dullness, both in front and behind, but this dullness is not at all marked—only moderate. We find that the breathing is not as distinct on the left side as it is on the right, still we can hear it. We find a friction sound over the whole of the left lung.

Now, what is the matter with the man? "Pleurisy with adhesions." Well, he is a pretty sick man for that, is he not? "He has in addition dilatation of the heart." Well, he is pretty sick even for that, for you see the dilatation does not apparently interfere with the circulation to any extent. He has pleurisy with adhesions, undoubtedly, but he would not be in the condition that he is in now if that were all, the other lung being in good condition. "Fibrous phthisis." Yes, he has, I presume, a form of phthisis, very often called fibrous phthisis. The name, however, is a misnomer, to a certain extent. You ought not to mean, when you say that, that the man simply has interstitial pneumonia. There are cases in which persons have developed interstitial pneumonia, and have the symptoms of phthisis, and may properly be said to have fibrous phthisis, but cases like this man's are quite different. He has some interstitial pneumonia, but what constitutes the essential part of his lesion is that there have been miliary tubercles developed through the left lung, and not as an acute process, but as a chronic one. They have not all developed at once, but more and more have been gradually forming, until now the whole of the left lung is probably pretty thickly studded with these hard, chronic miliary tubercles. Then, joined with these there has been a little fibrous phthisis, perhaps not a geat deal, because there is as yet no evidence of any great amount of consolidation of lung. The left lung does not seem to be consolidated to a great extent, although there is a lesion in it.

Then, with the production of these tubercles there has been developed a chronic pleurisy, and this chronic pleurisy has involved the whole surface of the left lung, and it is this which causes the friction sound and in part the dullness. The miliary tubercles do not necessarily give any dullness at all, unless there are a great many of them, or unless there is a good deal of fibrous tissue with them.

That, I presume, is the condition of the man's lung at the present time. He, again, is a patient who by all means should go into a hospital where he could be taken care of. I should treat him also, at first, in very much the same way that I should treat the girl with phthisis, who was in before. The immediate indication is to try to relieve the extreme anæmia, from which the man is suffering; and I should put him at once upon the use of iron and oxygen.

Medical Societies.

CASES OF POISONING FROM DRINKING IMPURE WATER.

BY JAMES H. HUTCHINSON, M.D.,

One of the Attending Physicians of the Pennsylvania Hospital.

Read before the College of Physicians of Philadelphia, May 3d, 1882.

During the past three months I have had under my care at the Pennsylvania Hospital a series of cases which presented a rather unusual set of symptoms, and which possess so much interest that I feel justified in taking up your time this evening with a brief account of them.

The patients were all Germans, and were all employed in a large sugar refinery in this city, at the foot of Bainbridge street, on the Delaware river front, where, however, none of them had worked more than two, or at most three weeks before the occurrence of the attack. The cases so closely resemble one another, that the history of one will suffice for my purpose. I have selected that of the first patient admitted, which was, moreover, much the severest of them all.

R. R., aged 21, born in Germany; single; shoemaker; was admitted into the men's medical ward of the Pennsylvania Hospital on January 30th, 1882. One of his sisters is said to have died of consumption, but with this exception, his family history is good. His own health has always been good until two weeks ago, when, without any apparent cause, he was seized with diarrhœa, attended with a good deal of prostration. He has had as many as ten to fourteen stools a day, and has also had at times nausea and vomiting, but is sure that he has never had fever. Yesterday the diarrhœa ceased, and he has had no passage since. Upon admission the patient is anæmic, and complains of excessive weakness, of vertigo, and of pains in his back and limbs. The tongue is dryish, and coated with a thin, whitish fur; the appetite poor, and the pulse slow; the temperature subnormal, 97°; there is no tympany. The examination of the heart, lungs, and urine gives negative results only; he was ordered a pill containing nitrate of silver gr. $\frac{1}{3}$, and opium gr. $\frac{1}{4}$, three times daily, and placed upon a restricted diet.

Feb. 2d. The patient's bowels have not been moved since his admission; he feels less weak than when admitted; his tongue is also less coated, but his temperature is still subnormal. The use of the pill was discontinued, and he was ordered a teaspoonful of Huxham's tincture, three times daily.

Feb. 20th. The bowels are now moved regularly; he does not appear to gain strength; he was, therefore, ordered cod-liver oil.

March 6th. Discharged cured.

I confess that when this case first came under my care I was puzzled how to explain the symptoms it presented. The presence of excessive prostration, with a history of diarrhœa lasting for two weeks, seemed to point to typhoid fever as their most probable cause. Against this hypothesis was the fact that the patient was positive in his assertions that he had not had fever at any time since he was taken sick, that none was present at the time of his admission or subsequently, and that there was no tympany or rose-colored spots. His condition called, however, for a supporting treatment, and I thought it best to restrict his diet to liquid articles of food.

The other cases came in rapid succession, and presented the same symptoms as the first case. There were in all of them prostration, slow, compressible and often dicrotic pulse, subnormal temperature, diarrhœa, sometimes accompanied by slight pain in the bowels, and absence of tympany. This similarity of symptoms appeared to indicate an identity of cause, and it was soon discovered that in addition to having been employed in the same refinery, they had been all subjected to an influence which seems to me

sufficient to explain the symptoms from which they suffered. It was found upon inquiry that water from the river Delaware is introduced into the refinery for use in cleansing the evaporating pans, and after being used for this purpose, it is returned to the river above the point, although at a considerable distance, from that at which it is taken.* The water is distributed throughout the building, and being more accessible to the workmen than the ordinary hydrant water, is freely used by them for drinking purposes. The water, although said to be filtered before being put to the use first referred to, is probably, from the presence of organic impurities, unfit to drink.

There can be but little doubt that the use of the water of the Delaware river, contaminated as it must be opposite Bainbridge street by sewage, was the cause of the singular symptoms observed in the six patients who came under my care. Impure as it was, it did not, however, produce typhoid fever, and my cases show that while impure water may produce prostration as great as that seen in this disease, it will not produce the fever itself, unless it contains the specific typhoid germs.

The symptoms presented by these cases seem to have indicated the existence of blood poisoning rather than of irritation of the bowels. The latter could hardly have existed without the presence of a certain amount of fever. The temperature records will show that at no time in any one of the cases was there any elevation of temperature above the normal. The stools, too, indicated the existence of relaxation rather than of inflammation; they were rather dark in color and watery, and never presented the ochrey yellow appearance of the stools of typhoid fever. The cases further show that persons may become accustomed to the use of an impure water, or that, at all events, it may cease to excite in them, after a certain time, any active symptoms. It will be remembered that all the patients had only recently been employed in the factory, and the effects of drinking the water had shown themselves very soon after they had entered upon their duties. The older hands drank the water with impunity.

The cases all did well, and required little treatment. Hope's camphor mixture being used in most of the cases to check the diarrhœa, and quinia or Huxham's tincture as a tonic.

It may be well to add that the attention of the proprietors of the refinery has been called to the supposed cause of the illness of their workmen, and they have taken the proper precaution to prevent the occurrence of further sickness among them by cautioning them against the use of this water for drinking purposes.

I have appended to this paper the histories of the remaining five cases which I had the opportunity of observing. They are drawn up from notes taken by Dr. J. M. Fox.

Case 2.—Diarrhœa with typhoid prostration; A. W., æt. 18; born in Germany, single, baker; admitted March 1st, 1882; discharged March 13th, 1882, cured. He came to this country last September; has always been very healthy until two weeks ago, when he began feeling weak and miserable, and to have headaches and diarrhœa, which have continued.

Upon admission has no fever; temperature subnormal; appetite poor; tongue slightly coated; some hebetude and slight headache; no fullness of abdomen; a few râles heard over apex of right lung; examination of heart and urine negative. Ordered quinine, gr. viij daily, and liquid diet.

2d. Tongue clean; only one passage from bowels; pulse slow, with a tendency to reduplication.

3d. Bowels not moved since; no fever; feels much better, but is still rather dull.

13th. Continued to improve, and is now well.

Case 3.—Diarrhœa with typhoid prostration; H. S., aged 28; born in Germany, single, laborer; admitted March 13th, 1882; discharged March 20th, 1882, cured. Has generally been very healthy; eight days ago he began to have diarrhœa, pain in the stomach and limbs, headache, and vomiting, and these symptoms have continued; has had as many as twelve loose stools a day.

He has been working in a sugar refinery, and is the second patient who has been admitted from there into the hospital within the last month and a half, with much the same symptoms, except that the prostration of the other two (R. R. and A. W.) was more marked.

He says that he has been in the habit of drinking the water that is pumped from the Delaware, which is very likely the cause of the trouble.

Upon admission patient feels weak and dull, has headache, vomiting, and diarrhœa; pulse weak and reduplicated (this was also the case with the other two patients); appetite good; tongue clean. Examination of heart, lungs and urine gives negative results. Hope's camphor mixt. f℥ ss. was administered as needed.

15th. Bowels are still loose, and passages are light colored; no more vomiting; diet has been restricted; camphor mixt. was stopped, and powdered opium gr. ¼, with oxide of silver gr. ⅛, were given three times daily.

19th. Diarrhœa has been checked, and he now feels and looks quite well. His temperature since admission, has ranged from 98° to 98½°

Case 4.—Diarrhœa with typhoid prostration; F. S., aged 31; born in Germany, laborer; admitted April 17th, 1882; discharged April 25th, 1882, cured. Has generally been very healthy. Two weeks ago, while working at a sugar refinery. he was taken with a pain in the bowels and diarrhœa, which have continued up to the present time.

Upon admission, patient was somewhat prostrated; has diarrhœa and tenderness in the epigastric region; the tongue is slightly coated in centre, moist; appetite poor; pulse slow; no fever. Heart, lungs, and urine normal. Ordered quinine, gr. viij. daily. Hope's camph. mixt. f℥ ss. as needed, and liquid diet.

April 20th. Diarrhœa has been checked, and he feels much better.

25th. Feels very well; bowels regular; appetite good. Temperature ranged from 98° to 98½°.

Case 5.—Diarrhœa with typhoid prostration;

* The water is taken from the foot of a long wharf, projecting into the river; it is returned at the point nearest the fact ry. These two points are distant from each other about 150 feet.

M. Z., æt. 26; born in Germany, laborer; admitted April 17th, 1882; discharged April 25th, 1882, cured. Eight days ago, while working at a sugar refinery, he began to have diarrhœa and pain in the bowels, and these have continued up to the present time.

Upon admission his face is slightly flushed, and he has a typhoid appearance; is somewhat prostrated; tongue coated in centre, moist; pulse slow; bowels were opened six times during the night. He has no fever, and there is no fullness of the abdomen. Examination of heart, lungs and urine gives negative results. Ordered Hope's camphor mixt., f℥ ss, to be given as needed, quinine, gr. viij daily, and l liquid diet.

23d. Feels very well: bowels regular; no pain; appetite is good. Temperature has ranged from 98° to 98½°.

Case 6.—Diarrhœa with typhoid prostration; M. W., æt. 19; born in Germany, single, laborer; admitted April 24th, 1882; discharged April 29th, 1882, cured. Has generally been very healthy. Came to this country eight months ago; two weeks ago he began working at a sugar refinery; about a week ago he was taken with diarrhœa, which has since become worse; has not had any nausea or pain.

Upon admission patient is slightly prostrated; face flushed; temperature also subnormal, 98°; tongue slightly furred, moist; pulse slow; appetite poor; bowels loose. Examination of heart, lungs and urine gives negative results. Ordered Hope's camphor mixt. f℥ ss to be given as needed.

29th. Diarrhœa has been checked, appetite has improved, and he seems very well again.

NORTHERN MEDICAL ASSOCIATION.

Remarks on the article presented by Dr. R. B. Glasgow (see page 648).

Dr. L Brewer Hall called attention to forms of clonic spasm, not classified as chorea, occurring as transient complications of many gross nervous lesions. This is instanced in hemiplegia. The study of these conditions may elucidate the pathology of choreic nystagmus, which may not necessarily be dependent upon cerebral lesion, is a functional affection, due, in very young individuals, to impaired vision, which is often the direct result of varied pathological states, like corneal opacity, lack of pigment in choroid. etc., etc.

Dr. G. B. Massey differs with the classification of chorea major and chorea minor. The former occurred in Germany during the middle ages, and is now, as then, an hysterical affection. Psychical impressions, which may variously be made, effect entire relief. The cardiac murmur, so frequently coexistent, is due, in a majority of instances, to anæmia. These murmurs yield to ferruginous preparations, combined with alterative and antileptic therapeusis. The routine arsenical treatment of Fowler's solution is the best, and should be administered in doses, as a rule, much larger than ordinarily exhibited. (Dr. Hall directed attention, incidentally, to the varying strength of different brands of Fowler, and considered this an important fact to be considered when ordering heroic doses.)

Dr. Daniel Longaker, referring to rheumatism as an etiological factor of chorea, does not consider its occurrence in children as rare as authorities would lead us to believe. He has two cases of acute articular rheumatism under observation at present, in children three and four years old.

Regarding the effect of chorea on pregnancy and parturition, Dr. E. W. Holmes narrated an account of a patient who, at the age of 14, first manifested choreic symptoms. They were limited to the hands, and were intensified at the catamenial epochs. When married there was no noticeable increase. During the eighth month of pregnancy she received a severe fright, which precipitated a general and severe form of the disease. Labor occurred at the proper time, and was not in the least complicated or characterized by irregularity. Three weeks subsequent to the accouchement no change in the disease was noticed.

Dr. Henry Beates, has under care a primipara, illegitimately pregnant, who suffered with marked manifestations of chorea, affecting principally the right limb and both arms. The muscles of the trunk occasionally, yet violently, contract. The first symptoms of the disease occurred before pregnancy, and were not aggravated by it. The exhibition of Fowler's solution, in the conventional doses, has effected complete cure. The labor progressed normally, and the patient, now two months later, has no symptoms of the disease.

Dr. Wittig reported an instance of a young girl, aged 15 years, who was subject to chorea. In course of due time the disease was cured by appropriate treatment. Some years later she married, and during pregnancy the disease recurred. At the second month abortion occurred and the disease continued for a considerable time, but eventually yielded to treatment. Reflex irritation such as accompanies entozoa and deranged function, general debility, etc., must invariably be considered in treatment. Regulation of bowels and skin should receive attention and analeptic measures be instituted.

Dr. C. K. Mills agreed with the author of the paper, that the name *chorea* was one applied to various pathological conditions. Extended clinical observation and some pathological experience, led to the belief that chorea was often due to cerebral lesion. It was not uncommon in cases of gross lesion of the cortex to see some choreic manifestations. In unilateral chorea, with hemi-paresis, it was difficult to accept any other view than that of a localized cerebral lesion, as embolism. Chorea associated with anæmia, rheumatism, traumatism and fright would usually be found to be due to cerebral disturbance. Extreme cerebral anæmia resulted sometimes in convulsions; anæmia milder in degree might give rise to choreic twitchings. Rheumatic meningitis sometimes occurs, and the motor cortex is irritated by the inflamed membrane. The etiology of traumatic delirium presents some analogies to that of chorea. An injury to the head resulted in meningitis, and delirium followed, because of cortical irritation. A similar lesion affecting the motor region only might result in chorea. Fright acted by causing cerebral vaso-motor spasm and anæmia.

Dr. Mills related some interesting cases of

local chorea—one which affected the muscles of the ear, another of facial chorea, in which choreic paroxysms occurred at intervals of several days. He referred also to habit chorea, and to hysterical, rythmical chorea, which is apt to be confounded with a form of sclerosis of the cord. The most successful routine treatment for chorea is the arsenical. When arsenic fails, cimicifuga, iron, or mild purgatives may prove efficient. Large doses of bromides may be of temporary service. Quinine is useful where a malarial element exists.

In answer to a question by Dr. C. A. Oliver, with reference to diaphragmatic chorea, Dr. Mills recalled one case, in which irregular diaphragmatic movements had occurred.

Periscope.

Inflammation of the Eyes in Newborn Children.

The *Lancet*, May 6th, 1882, says:—

Some years ago the above subject received the attention of the Congress of Instructors of the Blind which met at Dresden. Herr Reinhardt, director of the local blind asylum, on that occasion expressed his opinion that the majority of blind children had lost their sight through inflammation, and attributed its disastrous effects to the prevailing ignorance among the lower orders of the absolute need for skilled medical treatment in such cases. The statistics of twenty-two blind asylums in Germany for ten years (1865 to 1875) show that 40 per cent. of the patients therein received had lost their sight from this cause during their early infancy. In accordance with resolutions adopted recommending the diffusion of sound knowledge upon this important subject, several medical men in Germany have lately given currency, in the press, to their personal experiences. Dr. Colsman, of Barmen, an oculist, recently gave in the *Kölnische Zeitung* some details of interest, and referred to two cases in which each child had lost one eye before medical aid was called in. Dr. Samelsohn, of Cologne, in discussing the various features of this malady, remarks: "Inflammation of the eyes in the case of newborn children does not usually arise, as many consider, from unknown influences of the weather or from exposure to a too powerful light, but rather from the eyes at birth receiving the contact of a contagious substance, the sources of which are abundant among the lower classes of the population, particularly in large cities." According to Dr. Samelsohn's observations, the symptoms of this malady do not appear immediately after birth, but between the third and fifth days of the infant's life. The child, which has hitherto opened its eyes freely, now closes them obstinately against the light, and becomes restless; while a swelling of a more or less important character affects the inflamed eyelids, and from the opening of the lids there flows matter of a yellowish color. If this suppuration cannot be arrested the cornea is often destroyed, and the power of vision irretrieveably lost. With respect to the most effectual remedies, Dr. Colsman remarks that the eyes have been successfully disinfected "By dropping into the eyes, immediately after birth, solutions of two per cent. of carbolic acid or nitrate of silver, and by fomentations of a solution of salicylic acid during the first twenty-four hours, with a view of preventing the outbreak of the disorder."

Intussusception.

Dr. Thomas Cawley Eager records the following unusual case in the *Lancet*, April 15th, 1882:—

At 3.30 A.M., on January 7th, my assistant was sent for to see L. P., aged eight years, the daughter of a ticket collector at Working station. On arriving he found the child in a state of collapse, from which it never rallied, and died at 7.45 A.M. The history of the case was as follows: The child was running about in perfect health at 6 P.M. on the 6th inst., and being sent on an errand by her father was given a sweetmeat, in the form of a mouse, made of white and colored sugar. About an hour and a half afterward she was suddenly seized with intense pain in the abdomen, accompanied by vomiting of partially digested food; and the parents, thinking the attack was simply bilious in character, delayed sending for advice until the time mentioned. Not feeling satisfied as to the cause of death, and as the symptoms presented some of the appearances of irritant poisoning, I considered it advisable to communicate with the coroner, who ordered a post-mortem examination to be made, which took place on the 11th inst. at 12.45 P.M. On opening the thorax the lungs and heart were found to be healthy; but on opening the abdomen a very different state of affairs was disclosed, the intestines being gangrenous. The stomach was removed and opened, but presented nothing abnormal. On tracing the duodenum downward the cause of death was at once apparent; for about four inches from the commencement of the jejunum the gut was found to be intussuscepted for a length of 18 inches, and was gangrenous from that point to within 3 feet of the ileo-cæcel valve. The kidneys, liver, etc., were all healthy. The brain was not examined.

Remarks.—Experience teaches one that in intussusception, as a rule, the invagination of the gut is ileo-cæcal; that diarrhœa, with bloody stools, is present; and that generally the patient lives from three to six days. In this case, however, which is unique as far as my experience goes, we find, 1st, a great length of gut invaginated in an unusual position; 2d, a sudden, and not gradual, development of the symptoms; and, 3d, a fatal result happening within twelve hours of the first symptom.

Successful Sponge Grafting.

Dr. Norman Porritt relates the following case in the Edinburgh *Medical Journal*, May, 1882:—

The patient, 14 years of age, employed in a mill as a "firer," was coming down three or four steps, at the bottom of which was a rapidly revolving drum. In doing so he slipped, and fell with his right cheek upon the edge of the drum. The accident occurred on the 7th of November, 1881, and on admission to hospital, immediately after it, I found a pale, somewhat anæmic boy, extending obliquely across whose right cheek was an oval, charred cavity, four inches long and two inches in the greatest breadth, whence the margins converged to a point at each extremity. It had exactly the appearance of a burn, the result, no doubt, of the friction which occurred during its production. Poultices were applied, for which, as the slough began to detach itself, carbolic oil was substituted.

21st November. There is now a rather pale granulating cavity, one-third of an inch deep in the centre, of the shape and size above mentioned. Into this cavity a slice of sponge, prepared according to Dr. Hamilton's directions, was placed so as to fit it accurately and fill it completely, but without rising above the level of the surrounding skin. A piece of dextrin or protective silk was laid over the sponge, and the whole held in position by strips of plaster. Two thicknesses of boracic lint, some wadding, and a bandage, completed the dressing.

22d. The dressings were changed at 11 P.M., as discharge was oozing through them. The sponge is firmly fixed, and covered with odorless purulent fluid, while its edges are yellowish-white.

28th. The dressings are changed, and the wound irrigated daily. The surface of the sponge is black, and on gently pulling the lower part of it the side of the wound is dragged with it. The lower extremity appears incorporated with the granulations visible at the margin. The sponge is soaked in thin purulent discharge.

11th December. There are no indications of granulations pushing through the sponge, which now adheres very firmly. With the scissors a thin slice was taken from the surface, which caused blood to issue from the sponge beneath, and the portion then exposed was of a general faint pink color, no granulations, however, being visible.

21st. The sponge, since the last note, has been dragged more deeply into the wound cavity, and the pink hue is much more pronounced. One small pouting granulation protrudes through the upper portion of the sponge, and the discharge is much more abundant and more creamy.

26th. Many more tufts of granulations now show upon the surface, upon which the sponge tissue is not apparent to the eye, but can be detected by pulling at the surface with the forceps, when fragments of sponge are brought away. The whole has a much more intense red appearance.

9th January. The whole of the sponge structure, with the exception of very small particles, has disappeared, and a mass of healthy-looking granulations at the lower angle of which cicatrization has commenced, occupies the place of the sponge. The mass is the same size as the sponge and projects above the surface of surrounding tissues.

13th. The patient dismissed. The wound is now three-fourths of an inch long and one-fourth of an inch broad, and is healthy and granulating. Cicatrization is proceeding very rapidly indeed.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——We have received the Sixty-fifth Annual Report on the state of the Asylum for the Relief of Persons Deprived of the Use of their Reason.

——We have received the twenty-eighth Registration Report of Rhode Island. It is a most excellently prepared and comprehensive register of all the vital statistics of the State.

BOOK NOTICES.

Materia Medica and Therapeutics. Inorganic Substances. By Charles D. F. Phillips, M.D., Member of the Royal College of Physicians, etc., etc. Edited and adapted to the U. S. Pharmacopœia, by Laurence Johnson, A.M., M.D., Lecturer on Medical Botany, Medical Department of the University of the City of New York, etc. Volume I. pp. 298. New York: William Wood & Co. 1882.

This volume constitutes the April number of Wood's Library of Standard Medical Authors. It discusses the various inorganic materials used in the treatment of disease, and does it well. It will be found a valuable book for all who desire to be well posted in the therapeutics of inorganic drugs.

The Diseases of the Spinal Cord. By Byrom Bramwell, M.D., F.R.C.P. (Edin.), Lecturer on the Principles and Practice of Medicine and on Medical Diagnosis, in the Extra-academical School of Medicine, Edinburgh, etc., etc. pp. 300. Edinburgh: Maclachan and Stewart, 1882.

This is a very valuable book, that deserves to be read by all physicians. The author shows, by this product of his pen, that he has had ample opportunity to observe the subjects upon which he writes, and gives ample evidence that he possessed the ability to profit by this observation. The volume is most profusely and excellently illustrated. The style is clear and intelligible, and it is, taken altogether, a work that can be highly recommended to the profession.

THE
Medical and Surgical Reporter,
A WEEKLY JOURNAL,
Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	**$5.00**
Half-Yearly Compendium of Med. Science,	**2.50**
Reporter and Compendium, - - -	**7.00**
Physician's Daily Pocket Record, - -	**1.50**
Reporter and Pocket Record, - - -	**6.25**
Reporter, Comp. and Pocket Record, - -	**8.25**

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

D. G. BRINTON, M.D.,
115 South Seventh Street,
PHILADELPHIA, PA.

ENDOWMENT OF RESEARCH.

In an editorial, and a very able one, in a recent number of the *Lancet*, on the new "Association for the Advancement of Medicine by Research," we note the following:—

"We hope that it will confine itself to the encouragement of research, by its official support and its advice, and that no attempt at endowment will be made. Grants by the Royal Society and by the Scientific Committee of the British Medical Association are quite sufficient for this purpose, or, if not, they should be increased. There is no need for another body to take part in this work, and we venture to think that many subscribers whose names appear in the list would withdraw their support if the active endowment of research becomes a feature of the new Society."

These words may convey to the mind of the English reader ideas very different from those that it would tend to generate in the brain of a practical American. Therefore, perhaps, on this ground, we may be hasty in taking exception to them. If so, we apologize in advance. But it would seem that such advice is dangerous, and the very kind that ought *not* to be given to this new Association.

The old saying, that "money makes the mare go," is a vulgar but a very truthful and practical aphorism. Though some pretend that they do not care for money, yet this is, in truth, only a pretence. It is almost as natural for the large majority of men to desire and seek for money, as it is for them to eat. As we understand the meaning of this *endowment*, as referred to by the *Lancet*, it ultimately results in a pecuniary reward to some gentleman who has benefited and advanced his profession by very much hard labor.

In the first place, such a man deserves the reward, and in the second place, the expectancy of remuneration will have considerable influence in bringing many more investigators into the field, than would be found therein were *honor* to be the *only* reward of their labors. It might be objected to our view, that these men who labor for money are not in love with their study, and will, therefore, fail to pursue it earnestly and heartily. Our answer can only be that this is not so. There are many able men in the world who cannot afford to work for nothing, who have no reserve wealth, and must, perforce, make every hour of labor remunerative; while, again, there is a large class who, while they can afford to do so, yet will not labor for honor and fame alone, but must see some likelihood of a substantial remuneration before them.

Of course, there are enthusiasts, who would keep on working in some scientific pursuit with starvation staring them in the face, rather than turn to another occupation less congenial but more remunerative. But such men are very rare. If we desire anything valuable in this world, be it the product of mental or material agencies, we must pay liberally for it. Scientific research is no exception. If we desire deep investigation into the hidden truths of nature we must pay for it.

If it is well for some societies to make grants for certain purposes, we must confess an inability to recognize the logic that makes it wrong for another society (one more directly interested in the matter) to do the same.

If, then, we understand correctly the meaning of "Endowment of Research," we must commend it to all societies. Such a practice cannot become too common; it is impossible.

Notes and Comments.

Cerebral Lesions in Syphilis.

At a recent meeting of the Glasgow Pathological and Clinical Society (*British Medical Journal*), Dr. McCall Anderson showed a man aged 49. Twenty-four years ago the patient had syphilis. About fourteen years ago, after an attack of rheumatic fever, the patient had an attack of paralysis on both sides of the body—less severe, however, on the right than the left. His recovery was speedy, but never complete, slight rigidity remaining on the right side and some numbness on the left. These symptoms were aggravated after a second paralytic seizure, about two years ago, and only began to disappear when the patient was put on anti-syphilitic treatment. At the commencement of the first attack there was temporary unconsciousness. For the last three years there had also been a marked tendency to sweating on the left side of the face Dr. Anderson's diagnosis was a lesion of the motor tract of the brain of the left side, and of the sensory tract of the right side, the degeneration descending to the lateral columns of the cord. The only treatment employed was the inunction of mercurial ointment, which rapidly produced such an amelioration of symptoms that the patient left the hospital.

Transfusion of Saline Solutions in Hemorrhage.

A few years since Goltz put forward the opinion that in cases of grave and repeated hemorrhage death should not so much be attributed to the loss of red globules as to the state of vacuity of the arterial system. Taking up this idea, M. Schwartz, of Halle, in numerous experiments on dogs, remarked that when they were about to succumb to the loss of too large a quantity of blood, the transfusion of a saline solution rapidly augmented blood pressure and revived the animal. Is it not possible that this same process would prove beneficial in analogous cases in the human subject?

A New Vesicant.

Dr. José Armengue, of Barcelona, has lately brought to the notice of the profession a new vesicant, which in many respects would appear to be far superior to cantharides. The new material is derived from the *Œnas afer*, a coleopterous insect, which at certain seasons of the year appears in enormous quantities in many parts of Spain. From experiments which Professor Armengue has instituted, on his own person and on several medical students, he is led to claim for the *Œnas afer*, as a vesicant, the following advantages over cantharides: it is cheaper; it acts without appreciable pain; it is equally powerful; and it does not, so far as his experiments have yet shown, affect the genito-urinary system. If its non-inflammatory action can be established by further experiment, it is probable that the *Œnas afer* will be a valuable addition to the materia medica.

Disintegrated Renal Calculus.

Dr. Ralfe showed a specimen of renal calculus that had been passed in a state of disintegration, to the Pathological Society of London (*British Medical Journal*). It had been lodged in the right kidney for upward of three years, and had latterly caused so much pain that the question of nephrotomy had been discussed. When passed the calculus, which showed signs of erosion on its surface, was reduced to a mere shell. Alkaline treatment had been resorted to with a view of dissolving the stone, but without avail. Recourse was finally had to the plan recommended by Dr. John C. Murray, of Newcastle, of giving the patient considerable quantities (five to six pints daily) of soft water, i. e., filtered rain water. Occasional doses of turpentine and opium were also used, for the relief of colic and hæmaturia. After some months, pieces of grit and scales began to pass with the urine; and finally, at the end of two years the shell of the calculus was expelled.

Cerebro-Spinal Meningitis in a Newborn Infant.

At a recent meeting of the Medical Society of Athens, M. Bambas stated that he was recently called to attend a young woman in the last days of pregnancy who presented all the symptoms of cerebro spinal meningitis; fever, dry and burning skin, great pain over the occiput and in the temples, and vomiting. Notwithstanding appropriate treatment, the patient passed the night in a state of continual agitation, and after 3 A.M. ceased to respond to questions. The symptoms were the same as before, but there was considerable opisthotonos and involuntary passage of urine. At 11 P.M. labor commenced, and she gave birth to what appeared to be a perfectly healthy infant; but her own state continued grave, and she succumbed at 3 A.M.

At five the next morning M. Bambas was called to see the infant, whom he found with burning skin, very rapid pulse, stiffness of the neck and well marked opisthotonos. Death took place a few hours later. M. Bambas concluded that the infant presented a very acute case of cerebro-spinal meningitis.

Cure of Lichen Ruber Without Arsenic.

Up to the present it has been the custom to employ arsenic in the treatment of lichen ruber, and several months were required to obtain a complete cure with this medication.

Unna asserts that he has obtained results much more satisfactory without having recourse to arsenic. The treatment he recommends consists in frictions with the following ointment, over the affected parts:—

℞.	Hydrarg. bichlorid.,	gr. xv
	Ac. carbolic. pur.,	ʒ viss
	Ung. zinci oxid. benzoat.,	℥ xvj. M.

In grave cases this ointment should be used night and morning, the patient being afterward enveloped in woolen coverings. The condition of the mouth during the period this medication is employed should receive great attention, and gargles should be employed to prevent the development of mercurial stomatitis.

To prevent poisoning by carbolic acid the urine should be frequently examined, and as soon as any trace of phenol appears, large quantities of water should be administered.

Very soon after the first friction the painful itching which prevented the patient from sleeping should almost disappear and become supportable.

Under this treatment, out of six patients, two were cured after eight days; two others in fifteen days; and the two last, who had suffered from the disease more than a year, in three months.

Pulmonary Consumption—Recovery.

Dr. Francis Minott reports seven cases of pulmonary consumption in which recovery took place, in the Boston *Medical and Surgical Journal*, May 4, 1882. The first case was that of a hackman, aged 30. He presented undoubted evidences of phthisis. He was placed on the use of cod-liver oil, with croton oil to the chest externally. Two years subsequently no trace of the disease could be found.

The second was in a lady, aged 35, whose mother had died of consumption. She was given the same treatment and improved rapidly. When examined, four years from her first sickness, the physical signs of phthisis were all wanting, and her strength, color and flesh were perfectly good. She subsequently died, ten years after her first sickness, of consumption, which first made itself manifest only six months before death.

The other cases were treated much in the same way, and the results were equally satisfactory. In one case the influence of hygiene in checking the ravages of consumption was most marked. The patient was a young man of means. His left lung was sufficiently disorganized to allow of a perceptible depression of the chest wall on that side. He was ordered Churchill's hypophosphites, whisky, cold sponge bathing, and iodine to chest. He possessed the means to travel, to ride, and to lead that healthy life so particularly necessary for one whose lungs are weak. He recovered entirely, so that in three years' time he weighed one hundred and fifty-three pounds, and seemed perfectly well. He now imagined that he had heart disease, and became hypochondriacal, and finally died suddenly, while in a railroad train, after complaining a few minutes of faintness. No autopsy was made. These cases teach us that we need not despair when confronted with a case of consumption of the lungs; but they also indicate, that while cod-liver oil and other such tonic and sustaining remedies will do some good, we must look for the greatest benefit from hygienic surroundings. Therefore, unfortunately, is it that pulmonary consumption is a disease so fatal among the poorer classes, while those in affluent circumstances can provide the means wherewith to check its progress.

Treatment of Pertussis.

M. Dujardin-Beaumetz, in his recently published *Leçons de Clinique Thérapeutique*, recommends the bromides with chloral in the treatment of whooping-cough.

He gives, morning and evening, in a glass of milk containing a yolk of one egg, a dessert or tablespoonful (according to the age of the child) of the following mixture:—

℞.	Potass. bromid.,	ʒ ss
	Sodii bromid.,	ʒ j
	Ammonii bromid.,	ʒ ss
	Syrup. chloral. (Fr. cod.),	℥ iss
	Aquæ,	ʒ ij. M.

The Phosphates in Phthisis.

M. Dujardin-Beaumetz, in his clinical lessons on practical therapeutics, remarks that though the phosphates cannot be considered as specifics in phthisis, still they often prove useful in improving general nutrition.

He recommends the following mixture:—

℞.	Sodii phosphat.,	ʒ iss
	Potass. phosphat.,	ʒ j
	Syr. aurantii cort.,	℥ ij
	Vini (claret),	ʒ vij. M.

A wineglassful of this mixture may be taken after each meal.

This preparation gives excellent results, particularly when there is constipation and the quinine preparations are not well supported.

Correspondence.

Government Control of Medical Education.

Ed. Med. and Surg. Reporter:—

I have just read your editorial in the number for April 15th, 1882, p. 411, on "Government Control of Medical Education." This would be entirely contrary to the great characteristic of our American civilization, which is free competition. This free competition is as much needed in medical education as in any other interest. A government control of medical education would be liable to fail to place in the professional chairs those most fit to teach. Our present plan of free competition gives every man a chance to show his capability.

A much better plan, and one which will not do violence to the sentiment of fair play, is a board of examination which shall pay no regard to diploma but shall put every candidate for the practice of medicine to the test of such evidence of attainment as he can exhibit at the time of his examination.

This Examining Board may be entirely independent of compensation derived from the candidates examined, being employed by State authority and paid out of the State Treasury.

This will put no limit upon the number of schools, but will force them to such a standard as will enable their graduates to pass the necessary examination before the State Board of Examiners.

The law requires (in Illinois) all candidates for the practice of medicine who have not diplomas, or whose diplomas are not acceptable to the Board of Health, to come before this Board for an examination.

It is only necessary to abolish this distinction, and require all candidates for practice to come before a board appointed by State authority, to secure a high standard of attainment, while the teaching is left to free competition.

The form of our government, and our traditional regard for State rights, forbid the adoption by Congress of regulations in regard to the practice of medicine in the States, but the contagion of reform will ultimately carry a good system first adopted in one State into all the States.

Jacksonville, Ill. D. Prince, M.D.,

Does Vaccination Protect?

Ed. Med. and Surg. Reporter:—

In answer to Dr. Helm's request, in the Reporter of May 27th, 1882, I would state a personal case which may be of interest to him.

By the family records I was vaccinated successfully when about two years of age, though the evidence of it I could never observe, and again in 1869 I was inoculated with a crust, with evidently no effect.

During the epidemic of smallpox in 1874–5, in Charlestown, Mass., being at that time an assistant of Dr. E. J. Forster, the City Physician—having charge of many of his cases and frequently visiting the *pest* house there, I was, of course, repeatedly exposed to the disease, some of the cases being the most virulent form of smallpox. During this same epidemic I vaccinated several hundred patients, using fresh bovine virus, from which I obtained excellent results. I frequently inoculated myself with the same virus, obtained from different lots, but could obtain no effect whatever. To further test my susceptibility at that time I exposed myself still further by sleeping over night in the same bed and under the same covering with a relative, some three years of age, whose body was well covered with the pustules of advanced smallpox, without the slightest effect upon myself.

During the last epidemic in Chicago, 1882, I have used the vaccine virus from different localities with, generally speaking, good results, in the case of my patients, but with no result whatever upon myself.

In conclusion, to be brief, I believe, as the result of some experience with vaccination and variola, that there may be a time in man's life, of which we know naught, excepting by the test of vaccination, when, if he be exposed to the influence of smallpox virus, he will certainly contract the disease. The bare possibility of such an occurrence is sufficient to warrant us in vaccinating not only seven times, but seven times seven; for the good effects of a successful vaccination I most emphatically affirm.

Evanston, Ill. John H. Burchmore, M.D.

News and Miscellany.

AMERICAN MEDICAL ASSOCIATION

First Day.

The American Medical Association commenced its thirty-third annual session in the Opera House, St. Paul, Minn., June 6th. The Convention having been called to order by Chairman Stone, prayer was offered by Bishop Ireland. Governor Hubbard, of Minnesota, then welcomed the delegates, in an appropriate speech. Ex-Presidents of the American Medical Association, Drs. Sayre, of New York; Davis, of Chicago; Toner, of Washington, and Cole, of California, were invited to take seats upon the platform.

THE ETHICAL QUESTION.

The ethical question then came up, Chairman Stone stating that a number of protests had been received against the admission of delegates from the New York Medical Society, which would be read by the Secretary. Dr. Atkinson then read a number of protests, and referred to others by title, all bearing the same burden and expressing the feeling that the New Yorkers. by their action, had insulted the Association. The letters from Drs. Louis A. Sayre, New York, and Samuel D. Gross, Philadelphia, the latter expressing his regret at not being able to be present, and also referring in terms of censure to the recalcitrants, were received with a furore of applause. Dr. Sayre's letter, which is especially notable as coming from the heart of the disaffected, is as follows:—

THE SAYRE SCREED.

No. 285 Fifth Avenue, May 27th, 1882.

I. Martin Smith, M.D., *Secretary New York State Medical Society:*—

Dear Sir: I have just received from you my

certificate as delegate from the New York State Medical Society to the meeting of the American Medical Association, to be held in St. Paul on the 6th of June. As the State Society has ignored the Code of Ethics by which they were bound as members of the Association, I cannot see how they can expect their delegates to be received by an Association whose laws they refuse to obey and which must, therefore, refuse them admittance.

I therefore respectfully decline to act as its delegate, and hereby return my certificate.

Very respectfully,

LEWIS A. SAYRE, M.D.

These protests, as well as many others, were referred to the Judicial Committee. Vice President Dr. P. O. Hooper (in the absence of the President, Dr. J. J. Woodward, U.S.A.) then read the

OPENING ADDRESS.

He began by paying a high tribute to the absent President, after which he reviewed the history of the American Medical Association from its infancy until the present time, going over the ground thoroughly, and recalling the distinguished names that had been connected with it in the past, as its presidents.

After thanking the citizens of St. Paul for their hospitable reception, the speaker said:—

A generation of mortals have been born, lived and passed away, since the meeting of the convention which recommended the formation of this body. Most of those great spirits who inaugurated this enterprise, and gave form and substance to the ideas there entertained, can mingle with us no more forever. A few, upon whom "age sits with decent grace," still remain, revered for their wisdom and experience; and among these, facile princeps, is he (N. S. Davis) to whom, more than to any other one individual, we are indebted for our permanent foundation, and without mention of whose name there could be no appropriate reference to our beginnings.

In glowing terms he depicted the progressive spirit of our day, and dwelt upon the tendency to reform in medical education, now so happily prevalent in our country. The additions to medical literature in the last ten years, and their great value, was given due consideration. The establishment of a society journal was discussed, and the fact was noted that to this Society is due the credit of having introduced to the people of the different States the import ance of sanitary laws. In reference to the code of ethics, the speaker said:—

"There has recently been exhibited by a few, a disposition to be restive under the operation of certain portions of the code. It may not, perhaps, be becoming in me to discuss this matter here, as it will be for judicial investigation and decision; but I may be permitted to suggest that we should not retreat from our well chosen lines of defence. One mistaken movement would involve us in a whirl of inconsistencies, tending to place us in a false attitude and bring dishonor upon the profession. The broad lines of demarcation between the irregular and the true physician should never be obliterated. Our Association stands prominently forth in its high purposes, and its means of accomplishing these purposes are distinctly enunciated.

In conclusion, the Vice President said: I have attempted, by reference at least, to direct attention, gentlemen, to our present condition, our relation to science, and our duties. If anything I have said may appear presumptuous, you will charitably impute the blame to an earnest desire for the successful accomplishment of the aims of this Association, and a jealous regard for its honor and good name; believing, as I do, that if we go forward in the future as the noble men before us have gone, in the quest of truth, with earnest seeking and unselfish devotion, we will be of good in our day and generation, and fitly perform the work found to our hands to do.

Applause greeted President Hooper as he sat down, and Dr. William Brodie moved that the thanks of the Association be tendered the speaker and his address be published, and the motion prevailed.

Dr. Atkinson then read a letter of regret from the President, Dr. J. J. Woodward, who is in Europe, on account of illness. Dr. Cohen, of Philadelphia, suggested a cablegram be sent to Dr. Woodward, conveying the best wishes and regrets of the Society. This was received with applause.

THE TEMPERANCE CAUSE.

Dr. N. S. Davis, of Chicago, rose and said that he desired to present a preamble and resolution from the Women's National Christian Temperance Union. He was constrained to the presentation by the knowledge that the great woman heart, that pulses so dear to all, beat in unison with the sentiments expressed in the resolutions. They read as follows and were referred to the committee on medical jurisprudence.

THE W. C. T. U. RESOLUTIONS.

WHEREAS, Alcoholic intemperance is a prolific cause of disease. and prevention through the education of the people is one of the most powerful antidotes,

Resolved, That we approve teaching the children and youth in the schools and educational institutions in this country, as facts of hygiene, the physiological dangers and evils resulting from the use of alcoholic beverages, and

WHEREAS, It is the acknowledged duty of the State to provide for such education of the people as is essential to good citizenship,

Resolved, That we recommend the State Legislature to enact laws requiring the physiological dangers and evils resulting from the use of alcoholic beverages to be taught in all schools supported by public money or under State control.

One o'clock having arrived and the preliminary work of opening the Association having been satisfactorily accomplished, an adjournment was agreed upon, without objection.

Each afternoon was occupied with the meetings of the various sections, which we will give in full hereafter. In the evening the delegates were handsomely entertained by Governor Ramsey, Dr. and Mrs. Hand, Dr. Murphy, Dr. A. J. Stone and wife, Mr. and Mrs. A. J. Hill, and Hon. George L. Bicker, as well as at a public reception in the Metropolitan, which was a very elegant social event.

Second Day, Wednesday, June 7th.

The Association was called to order by the acting President at 10 A.M. Prayer was offered by the Rev. D. R. Breed.

This was followed by the Report of the Committee of Arrangements. Letters and telegrams from all over the northwest were read, asking every man, woman and child to visit the various sections. All that was necessary to insure them a royal welcome was to show their registration certificate as a member of the Association. A resolution was received from the City Council of Fargo, extending a most cordial invitation to the Association to visit that city and accept of its hospitality.

The Committee on Nominations was then announced. Dr. J. H. Packard, of Philadelphia, then presented the Report of the Committee on journalizing the Transactions of the Association. This Committee reported that it would cost about $13,000 per annum to establish and conduct a journal, and add that to propose to an Association varying in numbers and membership, from year to year, as the present body has hitherto done, and with an annual income never above $6000, falling sometimes as low as $2500, the assumption of an expense such as that just mentioned would be ridiculous. It is, therefore, recommended by the Committee to adopt the changes in the plan of organization, etc., proposed last year, by virtue of which the membership of the Association would be thrown open to all members of State and county societies, upon application, by the payment of an annual fee of $5, such membership to constitute the holder a subscriber to the journal. There are 90 000 practicing physicians in the United States; it may be supposed that more than one-half, say 50,000, belong to the regular profession; if 3000 would so subscribe the expenses of the journal would be assured. The journal they recommend to be controlled by a board of trustees, who shall appoint the editor, and they advise locating it as centrally as possible. The price to those outside of the Association to be $6. If the trustees can receive pledges of 2000 subscribers, they recommend that the publication be commenced at once.

The report was favorably received and the discussion of it was made the special order for the next morning. After some routine business, Dr. J. A. Octerlony, of Louisville, Ky., was introduced and read an address on

THE PRACTICE OF MEDICINE,

of which the following is but a brief abstract:—

Labor is not in a circle, but progressive, and labor in medical science has progressed rapidly, especially in more recent times. As new ideas have been evolved and new discoveries made, new names have been coined, until medical nomenclature is almost perfect. There has been more progress in this science in the past twenty-five years than in the 2500 years preceding. It must take things as it finds them, and not as it would have them, and deals with facts as they arise. The practice of medicine has undergone a complete revolution—it is not to-day what it was one hundred years ago. In 1827 Bright's disease of the kidneys was not understood, until that gentleman made the disease a special study, and his developments created a new era in medicine.

This illustration is sufficient to indicate the progress of the science in the last century, but it would require volumes to give all the advancement in each specific line. The medical history of the nineteenth century has yet to be written.

The process of crystallization of new knowledge into general law has been slow. The truths discovered have not been always received on first presentation, and the general skepticism of the age has invaded the realm of medicine; but those who have doubted the revelations of medical science have generally been those who were skeptical in regard to most other things which have been well established. Socialists are many, but their faith is very small. The foundations on which we are building were laid by those who preceded us. La Salins, Servetus, Harvey, and Knox form a bright galaxy, whose contributions to medical lore will survive the ages, while many whose names have never been inscribed on the roll of fame have bequeathed to us the best of their knowledge. Were a star to be blotted out now, its light would still reach us through the lapse of years; so when a good man dies, the light from his life is seen for many years after he passes away.

To more fully illustrate the subject Dr. Octerlony mentioned several common diseases in which the practice of medicine has been either modified or revolutionized. He took up the subject of inflammation, which was at first defined as "a morbid state, in which the parts seemed to burn." This term, however, has almost lost its value as a scientific term, being applied to so many things to many of which it has no real application. Afterward it was defined as consisting of four distinct elements, to which in later years was added a fifth, but the whole theory was overthrown when the circulating system was understood.

THE NERVOUS SYSTEM.

The brilliant workers in this field of medicine have not labored in vain, and nervous diseases of all kinds, and in their most intricate forms, are successfully treated. Pulmonary consumption is no longer the dread disease it was once considered.

"The lancet," some one has said, "is a little instrument of mighty mischief." But what the lancet was in former years to medical practitioners, the microscope is now to medical investigators, and its wonderful revelations in the infinitesimal world have kept pace with the revelations of the telescope in the starry world above us. Disease has been analyzed and its causes made known. Leprosy, that fearful scourge of the East in ancient times, has been shown to depend on a vegetable parasite. The microscope has shown that the exciting cause of typhoid fever is also a noxious parasite, and scarlatina and diphtheria fall in line under the same classification, being caused primarily by microscopic fungi. Malarial diseases were long referred to an element so subtile as to elude detection; but the same mighty instrument has shown that these disorders are due to a peculiar parasite, found only in malarial spots and nowhere else. Were the medical world to day to dispense with the

microscope and the vast amount of knowledge obtained through its use, a great part of our knowledge of disease and the proper method of treatment would be taken away from us.

Dr. Octerlony concluded his address by saying that all the important knowledge now in the hands of the profession, and the important discoveries in medical science, had been contributed by the regulars, and not by the irregulars, and expressing the hope that, in the years to come, a Newton in medicine would be found who would do for it what John Newton did for natural science.

At the conclusion of this address a partial report was made by the Judicial Council, through their chairman, N. S. Davis.

JUDICIARY COUNCIL EDICTS.

In regard to the Nebr ska State Medical Society, referred to us last year, the Council report that a careful examination of the documents and matters involved in the protest of certain members of the Nebraska State Association against the admission of said Society to representation in the American Medical Association, shows no proper cause for such protest at the present time, and the Council decide that the Society is entitled to full representation by delegates to this Association.

In regard to the resolution concerning the use of certain remedies controlled by a patent, copyright or trademark, which was reported from the Section on Practice of Medicine and Materia Medica, and by the Association referred to the Judicial Council, last year, the Council has decided that inasmuch as the resolution includes matters not referred to in the Code of Ethics, and said Code contains all that is necessary for the guidance of the medical profession, therefore the resolution should not be adopted by the members of the Association.

NO ADMITTANCE FOR NEW YORK DELEGATES.

In regard to the protest against the receiving of delegates from the New York State Medical Society, which was referred to us, the Judicial Council decide as follows:—

Having carefully examined the Code of Ethics adopted by the New York State Medical Society at its annual meeting in February, 1882, as furnished us by the Secretary of said Society, the Judicial Council find in said Code provisions essentially differing from and in conflict with the Code of Ethics of this Association, and therefore, in accordance with provision of Rule 9 of the By laws of this Association, decide unanimously that the said New York Society is not entitled to delegates in the American Medical Association.

This report was received with long continued applause.

UTERINE TUMORS.

The last paper at the morning session was read by Dr. H. O. Marcy, of Boston, who had for his subject Uterine Tumors. The method by which the lecture was demonstrated, the means used being a solar microscope and stereopticon, excited a large degree of interest, owing to the wonderful clearness and brightness of the subjects cast upon the screen.

After the termination of the lecture, in obedience to the expressed wish of many of the physicians, the inventor, Dr. L. D. McIntosh, of Chicago, explained fully the principles of this solar microscope, an explanation that was listened to with much interest and close attention. This solar microscope may truly be considered as a great aid to scientific investigation. By its aid physiology, pathology, histology can be studied, with illustrations of genuine sections. The circulation of the blood can be mirrored forth with startling distinctness; images of living animalculæ, minute insects and aquatic animals, with all their motions, thoroughly portrayed, and in cases where they are transparent, the beating of the heart and movements of the internal organs are vividly shadowed forth upon the canvass in a degree of perfection almost beyond belief. It is a combined instrument, and can be used as an ordinary monocular solar microscope and as a stereopticon. It is, however, very simple in its arrangement, there being no complicated parts that are liable to get out of order. The stereopticon proper is similar in appearance to the ordinary stereopticon, sunlight, however, being used, instead of artificial light. When the stereopticon objective is removed, and the working part put in place of the stereopticon objective, the solar microscope is then ready for use. If it is wished to be converted into a monocular, the working part is taken off and placed on a stand provided for the purpose. This combination adds much to the value of the invention, and its utility is very largely enhanced. Its use is not confined to physicians and scientists, for it is an instrument that should be in all educational institutions of the higher grades. Its use as a means of instruction is of great value, as an object can be shown with equal facility to a large class or audience as to a single person. In the matter of economy, without taking into consideration the superiority of its work, it is in advance of an ordinary stereopticon, as sunlight is cheaper than artificial light. Another feature is that it is exceedingly portable, and can be placed in position in a very short time. The ordinary power is that of 500 diameters, although, with higher objectives, it is capable of attaining a power of 1500 diameters. Taken altogether, it is truly an invaluable invention, and its use will be of an extended nature.

At 1 o'clock the Association adjourned, after passing a unanimous vote of thanks to Dr. Marcy for his entertaining lecture.

Third Day, June 8th.

The Association was called to order at ten o'clock. Prayer was offered by the Rev. M. N. Gilbert.

A number of communications were read, among which was the following from Georgia:—

At the thirty-third annual session of the Medical Association of Georgia, held in Atlanta, April 19th, 20th and 21st, 1882, the following resolutions, offered by Dr. James B. Baird, were adopted:—

Resolved, That the Medical Association of Georgia, in convention assembled, reaffirm its devotion to the time honored "Code of Ethics" of the American Medical Association, which has heretofore been its accepted chart, and shall henceforward be its trusted guide.

Resolved, That this body deprecates any and all attempts on the part of medical organizations to break down this honorable barrier between the regular medical profession and the vast and varied domain of quackery, and do earnestly protest against departures from the true spirit of the supreme law of the organized profession of the Union.

Resolved, That a duly attested copy of these resolutions be presented to the American Medical Association, in open session, at its approaching meeting. The above is a true extract from the minutes. WM. F. HOLT, *President.*

A. SIBLEY CAMPBELL, *Secretary.*

OFFICERS FOR THE ENSUING YEAR.

Dr. J. Foster Pratt, of Michigan, Chairman of the Committee on Nominations, presented the report of that Committee, which is as follows:—

President—Dr. John L. Atlee, Lancaster, Pa.

First Vice President—Dr. Eugene Grissom, North Carolina.

Second Vice President—Dr. A. J. Stone, St. Paul, Minnesota.

Third Vice President—Dr. J. A. Octerlony, Louisville, Kentucky.

Fourth Vice President—Dr. H. S. Orme, California.

Treasurer—Dr. R. J. Dunglison, Pennsylvania.

Librarian—Dr. Wm. Lee, Washington.

Members of Judicial Council—Drs. N. S. Davis, Illinois; J. M. Brown, United States Navy; X. C. Scott, Ohio; M. Sexton, Indiana; N. C. Husted, New York; Wm. Lee, Washington, and J. E. Rives, West Virginia.

This report was referred back to the Committee for correction, because it contained the names of absentees.

The Committee also announced that Cleveland had been selected as the place of meeting for next year.

The President announced, at this stage of the proceedings, that the time had arrived for the consideration of the special order, which was Dr. Packard's report in reference to the establishment of a journal of the Association.

Dr. Davis, of Chicago, said that although he was a member of the committee which made its report yesterday, upon reflection he was convinced that some amendments were required, and he therefore offered the following amendments:

Resolved, That the interests of the Association would be promoted by the publication of its transactions in a weekly medical journal under its own control, instead of in an annual volume, as heretofore, provided it could be done without involving pecuniary embarrassment, or so far engrossing its funds as to prevent the annual encouragement of original investigation by its members.

Resolved, That so much of the report of the Committee on Printing the Transactions as relates to the increase of membership of this Association by application from members of State and local societies be and the same is hereby approved.

Resolved, That so much of the report of the Committee on Journalizing the Transactions of the Association as relates to the appointment of a board of trustees, nine in number, and their duties, be and the same is hereby adopted, and that the president of the Association should appoint a special committee of seven to recommend to this meeting of the Association the names of nine members for election, to constitute said board of trustees.

Resolved, That the board of trustees so appointed be requested to agree upon a plan of a medical journal, to be called the *Journal of the American Medical Association*, and to send circulars explaining such plan, and asking pledges of support by actual subscriptions, to the members of the medical profession throughout the whole country, and thereby ascertain as reliably as possible what degree of support the proposed journal can have as a basis for commencing its publication; and that said board also proceed to ascertain and agree upon the best methods of publishing said journal, the best editorial services it can secure to take charge of the work, and the best plan for its issue.

Resolved, That said board of trustees be and are hereby instructed to retain, under all circumstances, in whatever plans or contracts proposed for adoption, entire control over the advertising as well as other pages of the journal that is proposed to be established, and that said board report in full at the next meeting of this Association, the plans upon which it has been able to agree, together with the response of the profession to its circular asking actual subscriptions to the proposed journal, and that the constitutional amendments proposed by Dr. Packard last year be continued upon the table until the report of the board of trustees is received and acted upon.

Resolved, That the Treasurer of this Association is hereby authorized to pay out of funds in the treasury the necessary expenses of the board of trustees in printing and distributing its circulars and in conducting its proper correspondence.

Resolved, That the Committee of Publication proceed to publish the proceedings and transactions of the present meeting in a volume as heretofore, using all diligence to give it an early distribution to those entitled to receive it.

Dr. Davis supported his amendments in an earnest speech, and they were equally as earnestly seconded by Dr. Brodie, of Michigan, and were unanimously adopted.

Subsequently the president appointed the following-named delegates as a committee to appoint the board of trustees, in accordance with the resolutions, viz.: Dr. L. A. Sayre, of New York; Dr. J. M. Toner, of District of Columbia; Dr. J. Foster Pratt, of Michigan; Dr. R. J. Dunglison, of Pennsylvania; Dr. Robert Battey, of Georgia; Dr. W. J. Peck, of Iowa; Dr. H. O. Marcy, of Massachusetts.

Dr. Gihon offered the following resolution, which was unanimously adopted:—

Resolved, That the American Medical Association heartily endorses and commends to Congress the proposition of the Surgeon General of the Navy, to establish at Washington, in connection with the Bureau of Medicine and Surgery of the Navy, and in co-operation with the American Public Health Association and the American Medical Association, a National Museum of Hygiene, which shall exhibit the history and progress of

sanitary science by a collection of publications, articles, models, drawings, etc., illustrating defects and improvements in food, in water supply, bedding, clothing, marine architecture, house and hospital construction, and removal of *excreta* and refuse, culinary, laundry and bath facilities, and for physical culture and exercise, and whatever else tends to the preservation of health and the prevention of disease.

Resolved, That this Association earnestly urges upon Congress the appropriation of the sum of $10,000, which has been recommended for the purchase of exhibits and their consequent care and preservation; and that the Permanent Secretary shall, without delay, send a copy of these resolutions to each member of the Senate and House of Representatives, in Congress assembled.

Dr. Davis offered the following, which was adopted, and the Secretary instructed to forward a copy of the same to each member of Congress:—

To the President and Members of the American Medical Association:—

WHEREAS, There are now employed between sixty and seventy physicians in the United States Indian Service, by authority of the Secretary of the Interior; and

WHEREAS, All physicians appointed to positions in the U. S. Indian Service are required to be graduates of some regular medical college; and

WHEREAS. There are now between 150,000 and 200,000 Indians depending entirely upon these appointed physicians for all medical and surgical treatment; and

WHEREAS, The present humane policy of the government is rapidly advancing the Indian civilization, thereby lessening the dependence in and consequent power of the "Indian Medicine Man," and greatly increasing the demand for and labors of the regularly qualified physician; therefore be it

Resolved, That the Constitution of the American Medical Association be so amended as to provide for the admission to its membership of two delegates from the medical bureau of the United States Indian Service, to be nominated by the surgeon-in chief of the Indian medical bureau and appointed by the Secretary of the Interior.

Resolved, That this resolution shall take immediate effect.

Dr. Toner, of Washington, submitted the report on necrology, which was referred to the Committee on Publication.

METEOROLOGICAL AND CLINICAL RECORDS.

Dr. Davis, from the Committee on "Atmospheric Conditions and their Relations to the Prevalence of Disease," reported that, in accordance with the action of the last annual meeting, stations of observation had been established at Boston, New York, Philadelphia, Baltimore, Charleston, New Orleans, Cincinnati, Pittsburgh, Chicago, St. Paul, Denver, and San Francisco. The committee secured the services of Prof. J. H. Long, to prepare the material and supervise the work for determining the relative proportions of the ozone and other active oxidizing agents in the atmosphere in the several localities. Through the efforts of Prof. Long, a number of eminent professional men of the country were secured to coöperate in the work, in which the United States Signal Service was also induced to coöperate, and to which the committee acknowledges itself under great obligations.

After reciting details of the work accomplished, and its undoubted value to medical science, the report recommends its continuance, and that it may be made still more efficient, that Professor Long be engaged, at a compensation of $500, to personally supervise the laboratory work during the coming year. The actual expenditures of the committee were $209 72, leaving $290.28 of the sum appropriated for the purpose unexpended, which will enable the committee to continue its work another year as prosecuted the past year, but the committee cannot make such other investigations as it seems to it essential should be made.

The report closed with the presentation of two resolutions, one for the continuance of the committee, with the unexpended balance of the appropriation of last year to remain at its disposal, and the other recommending an appropriation of $500 for the employment of Professor Long, as above suggested.

The resolutions were adopted.

Dr. W. A. Byrd, of Quincy, Ill., Chairman of the Section of Surgery and Anatomy, read a paper, which was referred to the Section of Surgery and Anatomy.

Dr. A. L. Gihon read an address on "State Medicine," after which the Association adjourned.

Fourth Day, June 9th.

The Association was called to order at ten o'clock, and prayer was offered by the Rev. E. D. Neill.

A final report was made by the Chairman of the Committee of Arrangements.

The Librarian presented his report, showing that the library contained about 4448 volumes, inclusive of pamphlets.

TREASURER'S REPORT.

Dr. Richard J. Dunglison, of Philadelphia, Pa., the Treasurer, made the following report, which was adopted:—

The Treasurer has the honor to report a balance in the treasury, at this date, of $1141.38. In the statistics furnished by him last year, to the Committee on the President's Address, which was really a report, or journalizing of the Transactions of the Association, the fluctuations of membership were distinctly exhibited. These figures, published in the last volume of *Transactions*, may be considered as still further verified by the experience of the past year. The question to which the Treasurer is compelled to reply more frequently than any other, in the course of a voluminous correspondence with members of the Association, is, "Why do you write to me as a permanent member?" or, "When was I elected a permanent member?" I would, therefore, state, for the information of all those present at the meeting at St. Paul, that every one who attended at that place, as a delegate from a medical society, will thenceforth become, from the very fact of such at-

tendance, a permanent member of the American Medical Association, who should annually pay five dollars to the Treasurer, as his dues to that body, according to the rules of that Association, expressly stated and printed in each annual volume of *Transactions*. As copies of the annual Transactions for previous years may still be obtained, it is suggested that those who have neglected to pay their dues at any time previous to the present year will communicate with the Treasurer, who will cheerfully respond to all inquiries, and inform them as to the volumes which are still in print and procurable from him.

EXPERT TESTIMONY.

Dr. Gihon called up his resolution on expert testimony, which had been laid on the table on Thursday, and offered the following as a substitute, which he said obviated the objections made to the original resolution:—

Resolved, That it is the sense of the American Medical Association, that it will be conducive to justice and the dignity of the profession, if medical expert testimony can be presented to the courts without having the appearance of being biased by any intention to influence either side of a case, but simply to state scientific facts.

The resolution, after a little running debate, was unanimously adopted.

SALARY OF THE SECRETARY.

The salary of the Permanent Secretary, aside from his expenses, was fixed at $1000 per annum, after some discussion, and Dr. Toner, of Washington, gave notice that at the next annual meeting he would offer an amendment to the by-laws, so that a secretary could be elected who would serve without pay.

Dr. Keller, of Arkansas, moved that the secretaries of the State Societies send annually to the Secretary of the American Medical Association a list of the members dropped from the State Societies. Adopted.

EVERY OTHER MEETING TO BE HELD IN WASHINGTON.

Dr. N. S. Davis introduced the following:—

Resolved, That after the next annual meeting the permanent interests and influence of this Association would be best promoted by again holding every second meeting in Washington, as its home on common national ground, and not as invited guests, while each alternate meeting should be held in such section of the Union as would be most useful in promoting the society organizations in all parts of our country. Adopted.

The following trustees, to found and conduct the journal, were announced:—

For Three Years—Drs. Davis, Chicago; Moore, New York, and Toner, Washington.

For Two Years—Drs. Campbell, Georgia; Packard, Pennsylvania, and Connor, Michigan.

For One Year—Drs. Hooper, Arkansas; Garcelon, Maine, and McMintry, Kentucky.

Dr. Brodie, of Kentucky, then offered a series of resolutions, expressing gratitude to the citizens of St. Paul for their hospitality. The resolutions were seconded by Dr. N. S. Davis, of Chicago.

The session then listened to an interesting address from Dr. D. H. Goodwillie, of New York, Chairman of the Section on Dentistry, on that important subject.

He spoke respecting the divisions of the Section, which naturally separates itself into a number of branches. These divisions are dental art and oral surgery. The first is nearly all mechanical in its nature. The second includes the treatment of all diseases of the mouth. To the proper practice of the latter it is necessary that there be added the experience of the former, with a practical knowledge of medicine and surgery. Such knowledge should be supplied from the chairs established in all our medical colleges, the practical department to be supplied by infirmaries and hospitals to give this knowledge. He illustrated the many diseases of the mouth and associate parts by cases in his own experience, exhibiting diagrams, photographs, instruments, and over twenty wax models of notable cases. Among them were inter-nasal and inter-oral extirpation of the bones of the nose and jaws, with a reproduction of bone without any deformity.

DELEGATES TO FOREIGN SOCIETIES.

The President then announced the following as delegates to the foreign societies: Drs. T. A. Emmett. D. Lewis, W. M. Carpenter and E. M. Brush, New York; and J. M. Da Costa, Pennsylvania.

Dr. N. S. Davis then escorted the President elect, Dr. John L. Atlee, to the platform; he was greeted with loud applause, and when introduced made the following remarks:—

Gentlemen of the American Medical Association:—It is with no ordinary emotions that, by your partiality, I occupy a chair that I have seen filled by a Chapman, a Warner, a Stevens, a Knight, and a host of worthies, living and dead, who were and are the ornaments of our profession. I beg you to accept, gentlemen, my heartfelt thanks for the honor you have conferred upon me. I accept it also with gratitude, as a tribute to the memory of a dear brother, who, were he living, would more deservedly occupy this position. My chief motive in coming here on this occasion was to assist in carrying out the instructions unanimously given by the Lancaster County Medical Society, to uphold the honor and dignity of our noble profession by putting the seal of condemnation upon the recent action of a State Society, the sanction of which would have given character to a system of practice derogatory to common sense and professional integrity. All honor, gentlemen, to the report of our Judiciary Committee. In the performance of my duties I shall endeavor to be firm and impartial, and I trust that I may be supported by your kindness and courtesy in trying to uphold the right.

The thanks of the Society were tendered to the retiring President, Dr. P. O. Hooper, Arkansas, by a standing vote. That gentleman responded feelingly, and at 12 40 o'clock the motion to adjourn was made by Dr. Toner, and the thirty third annual meeting of the Association was declared adjourned.

—On p. 633, 2d col., line 14 from bottom, for ext. felic. marisarth, read *ext. felicis maris æth.*

Medical Society of New Jersey. One Hundred and Sixteenth Annual Meeting, held at Asbury Park, May 23d and 24th, 1882.

TUESDAY, MAY 23d. FIRST DAY.

The Society convened in Educational Hall, Asbury Park, at 4 o'clock P M., and was called to order by the President, Dr. L. W. Oakley, of Elizabeth.

The Committee on Organization reported lists of delegates from the various District Societies in the State. The report included delegates from every District Society in the State, excepting Atlantic and Salem.

A cordial welcome was extended to the Society by Dr. J. H. Hunter, on behalf of the Committee of Arrangements, and by James A. Bradley, Esq., of Asbury Park, on behalf of the citizens of the Park.

Dr. Amos B. Pann, delegate from the Medical Society of Massachusetts, was formally presented to the Society, and invited to take part in its deliberations.

Dr. H. R. Baldwin, Chairman of the Business Committee, reported as follows:—

The Committee on Business recommend the following order:—

TUESDAY, 4 O'CLOCK, P.M.

Prayer. Report of Committee on Organization. Report of Committee of Arrangements. Reading of minutes of last Annual Meeting. Report of Committee on Business. Report of Delegates to Corresponding Societies. Report of Committee on Ethics and Judicial Business. Announcement of Committees by the President.

7.30 O'CLOCK, P.M.

President's Address. Report of Standing Committee (Five minutes allowed each member for remarks upon the same). Report of Corresponding Secretary. Report of Committee on Unfinished Business. Half an hour allowed for discussion upon some subject suggested at previous meeting.

WEDNESDAY, 9 O'CLOCK, A.M.

Report of Committee on Treasurer's Accounts. Receiving and acting upon applications for Degree of M.D. Report of Committee on Honorary Members, and Honorary Degree of M.D. Reception of Delegates from Corresponding Societies. Investigation of By-Laws and receipt of communications from District Societies. Essay—by third Vice-president. Reading of such papers as approved by Business Committee. Recess from 1 to 3 o'clock, for dinner. Continuation of previous order. Report of Nominating Committee. Election of Officers. Miscellaneous Business. Adjournment.

The report was adopted.

The following was adopted:—

Resolved, That the Medical Society of New Jersey reaffirms its allegiance to the Code of Ethics of the American Medical Association, and views with distrust any effort on the part of legally constituted societies to deviate from or antagonize its provisions.

Communications from Hudson, Camden and Mercer District Societies were received and referred to Committee on Judicial Business.

The death of Dr. John Wright, of Freehold, was announced, and Drs. Woolverton, Phillips, Neil, English, Weeks and Dunham were appointed a committee to attend his funeral.

The following committees were announced:—

Nominating Committee—S. S. Clark, chairman, D. A. Currie, L. Jamieson, H. G. Taylor, J. S. Whitaker, G. A. Van Wagener, G. C. Laws, W. P. Watson, M. Abel, H. M. Weeks, D. C. English, J. S. Long, J. G. Ryerson, C. A. Harris, L. D. Tompkins, J. Miller, H. H. James.

On Treasurer's Accounts—J. E. Arrowsmith, W. A. P. Neil and H. H. James.

Adjourned until eight o'clock in the evening.

EVENING SESSION.

President in the chair. The president read the annual address, the subject of which was "Medical Education."

Report of Standing Committee. Dr. Kipp, chairman, then read the Report of the Standing Committee.

A résumé of the medical history of the State for the past year, as gathered from the various county reporters, shows an increase of malarial diseases throughout the State; from various portions come the report of typho-malarial cases, with a low rate of mortality.

Smallpox is reported from certain portions of the State, with a mortality of about 30 per cent. The epidemic is decidedly on the decrease.

Diphtheria and scarlet fever have been present throughout the northern counties, with a low death rate.

Typhoid fever was reported from the southern portion of the State, being particularly fatal in Ocean county.

An epidemic of catarrhal disease was reported from Camden city, peculiar in character, affecting all the mucous membranes, but of a mild type.

Dr. Hunt reports certain cases of diphtheria where, the date of infection being known, the period of incubation was determined as five days.

The following essays were reported as received by the Committee: Dr. Welch, Treatment of Uterine Hemorrhage. Dr. St. John, Diagnosis of Infantile Diseases. Dr. Currie, on Wet Nurses.

An investigation of the workings of the new medical law shows that it has not been put to the test, no convictions having been obtained, and the irregular practitioner flourishing as usual.

From Essex is reported the formation of a Society for the Relief of the Widows and Orphans of the Medical Men of New Jersey.

The deaths for the year were Drs. Wilmarth, S. S. Marcy, C. T. Morrogh, H. S. Clew, H. S. Harris, T. P. Dickerson and T. H. Studdiford.

The Treasurer reported as follows:—

RECEIPTS—

Essex	$196.00
Hunterdon	28.00
Warren	32.00
Middlesex	28.00
Union	80.00
Sussex	50.00
Monmouth	60.00
Burlington	66.00
Passaic	80.00
Hudson	82.00

Bergen	34.00
Cumberland	34.00
Camden	78.00
Morris	64.00
Somerset	24.00
Gloucester	12.00
Ocean	10.00
For diplomas	15.00
For interest	38.00
On hand from last report	951.72
Invested in U. S. Bonds	900.00
In Savings bank	850.00

Disbursements—	$
To S. Wickes	11.76
W. Elmer, Jr.	8.16
Wm. Penn, Jr.	9.00
Jos. Parrish	18.20
J. Toombs	7.25
Telegram	1.10
E. P. Townsend	3.00
C. J. Kipp	617.88
S. Wickes	1229.83
	$1906.18

Adjourned until Wednesday, at nine o'clock.

WEDNESDAY, NINE O'CLOCK.

The Society re-assembled. President in the chair.

Dr. Ryerson, in behalf of the Fellows, made the following report:—

PRIZE FOR ESSAY.

The Fellows of the Medical Society of New Jersey present at Asbury Park, at the meeting there of the Society, hereby propose that the Society shall offer annually, if possible, or at least biennially, a prize of one hundred dollars to the members of the several District Societies of the State, for the best essay on some selected subject connected with medical science or art; and that they will deposit, annually (or at least biennially), with the Society treasurer, the funds necessary for that purpose.

The method of competition for and of awarding this prize shall be as follows:—

A committee of three shall annually be constituted, to be called the "Fellows' Prize Committee." The retiring president of the Society shall be, *ex officio*, its chairman; a Fellow selected by his associates shall be the second member, and the third shall be a member of a District Society (not a Fellow of the State Society), selected annually by the Society's Nominating Committee. At the session of the Society when this committee shall be constituted, it shall select and announce to the Society, and promptly to each District Society, a subject for the competition for the ensuing year. And during this same year it shall adjudicate upon the essays of the previous year, which shall have been handed in to its prospective chairman (then president of the State Society) not less than two months before this same session when it was constituted.

Each essay shall be signed with an assumed name, and have a motto, both of which shall be endorsed on a sealed envelop, to accompany the essay, containing the author's name, residence, and District Society; and none of these envelops shall be opened by the Committee until after its award, and then only those bearing the mottoes and names appended to the successful essays. The committee shall select the first two essays in order of merit, reference being had, not only to the subject matter, but to the language and style of the author. To the first they shall award the prize of money, to the second, that of honor able mention. They shall notify the successful authors to be present at the next annual meeting of the State Society, and give to the President the names of these authors, with their assumed names and mottoes.

The President shall announce to the Society, at that annual meeting, the authors, with their mottoes and nommes de plume, and before the whole Society, with some suitable ceremony, shall make the awards. The unsuccessful authors shall receive back their essays, upon their identification to the Chairman of the Committee, but the successful essays shall be the property of the Society, and shall be published in the "Transactions." No award shall be made unless the merits of the essays shall be of a decided character; and in this case the money shall remain in the treasury, until applied for a subsequent award.

The Fellows then announced the following subject, for the ensuing year, viz: "The Importance of Exploration of the Urine, both Chemical and Microscopic, as an Aid to Practice, and the Relation of Hæmaturia to Diseased Process."

Upon the nomination of the Fellows, the following Committee of Adjudication was appointed for the ensuing year: L. W. Oakley, *ex-officio* chairman, Henry S. Baldwin and James S. Green.

The report was accepted and the recommendations, by vote, were unanimously adopted.

The committee appointed to report upon the comparative value of humanized and bovine vaccine virus, and the best security for their purity, respectfully submit that they have received communications from the reporter of only one District Medical Society, Dr. Snowden, of the Camden District Society, and that the question was discussed at one of the meetings of the Mercer District Medical Society. Dr. Snowden writes that he had endeavored to obtain the opinion of each member of the Camden District Society, and that three-fourths of those from whom he had received replies preferred humanized virus. Most of these gentlemen are residents of the city of Camden, where a severe epidemic of variola prevailed more than a year ago. He writes that the objections to bovine virus are its want of reliability and the irregularity of the results obtained. At the discussion at the meeting of the Mercer District Medical Society there was a pretty general agreement as to the want of reliability of the bovine virus and the irregularity in the development of the vaccine disease resulting from it. Your committee have very little to add. In their own experience they have had a large percentage of failures in the use of bovine virus in primary vaccinations, the operation having to be repeated once, twice, or oftener. The period of development they have found to be by no means uniform, and the local and constitutional effects have often been severe and troublesome. They

prefer well selected humanized vaccine; but on the outbreak of an epidemic of variola they recognize the necessity of recourse to bovine virus, and the renewal of stocks of humanized vaccine requires occasional resort to it. The only security now existing for the purity of bovine virus is the prevailing standard of commercial morality, a very unsatisfactory ground of security. Your committee are of opinion that the establishment of a vaccine farm under the direction and control of the State Board of Health would afford a better and more reasonable security for purity and reliability of supply of bovine virus; and that the organization of the State Vaccine Establishment might prove to be a wise expenditure of public money.

JOHN W. WOOLVERTON,
WM. ELMER, JR.,
J. L. BODINE,
Committee.

Dr. D. C. English read a paper, entitled, "The Prevention and Limitation of Epidemics."

The writer called attention to the necessity of a public education in sanitary science, through the public schools; to the necessity of general legislation for the establishment of strict quarantine against infected ports, and of State legislation quarantining infected houses and keeping pupils from such houses out of the schools.

He spoke of the good work our own Board of Health has effected, the efficient legislation we possess, and called upon the medical profession to bring to bear its influence in such matters upon the masses, for the purpose of creating a public opinion in favor of measures of sanitary reform. That they should favor drainage, proper sewerage, pure water supply, isolation of sick, vaccination, and all other measures looking toward the limitation of epidemics.

The degree of Doctor of Medicine was conferred upon A. G. Schuhl, of Jersey City, and Vincent Nager, of Newark.

The report of the Committee on Honorary Membership was received.

Dr. Barker, of Morris, read a paper, entitled the "Vaccination Question," which was well received and a copy requested for publication.

A discussion upon the subject of Vaccination, in which many of the members took a part, was then entertained. There appeared to be quite a divided opinion as to the comparative value of humanized and bovine virus.

Dr. Chandler, of South Orange, read an interesting paper on Nerve Stretching.

After a general description of the anatomical lesions, there was given a valuable table of three hundred cases, with the results in neuralgias, spasmodic affections, tetanus, locomotor ataxia, etc., and finally a comparison and discussion of the general opinion of the operation.

The lesions caused by the operation are a loosening of the nerve in its sheath, extravasation of blood in the sheath, dilatation of the blood vessels, rupture of a portion of the nerve fibres, and, occasionally, nutrition changes. Stretching acts especially to interrupt the sensitive current, but allows the motor current to pass. The motor current and reflexes are more affected by centrifugal than by centripetal traction. Stretching acts on the nerve centres, producing certain dynamic changes, and occasionally local disturbances, more or less persistent.

There was a table given, of three hundred and twenty cases, as follows:—

Sciatica	57 cases,	91 p. c. cured.
Neuralgia of fifth pair	27 cases,	48 p. c. cured.
Traumatic neuralgia	16 cases,	75 p. c. cured.
All other neuralgias	33 cases,	66 p. c. cured.
Mimic spasm	13 cases,	85 p. c. cured.
Torticollis	10 cases,	60 p. c. cured.
Traumatic tetanus	49 cases,	20 p. c. cured.
Locomotor-ataxia	49 cases,	32 p. c. improved.

Cases of peripheral paralysis, and epilepsy with aura, have been greatly benefited.

In concluding, the Doctor said, "While nerve stretching may not accomplish all that its most ardent advocates claim for it, we feel confident that an operation that develops so much statistical strength has enough of real merit to outlive opposition, and take its place among accredited surgical operations."

Dr. Ill, of Newark, read a paper on Laceration of the Cervix. He reported forty-four cases, with thirty-nine cures, and five cases of non-union. Of these, thirty-seven were relieved entirely of the symptoms. The symptoms noted as following the lesion were anteversion, retroversion, subinvolution, complete prolapsus of body, chronic ovaritis, fungoid degeneration of endometrium, menorrhagia, pain on connection, and loss of sexual desire. This last symptom the writer had specially examined. It was present in thirty-four cases, and was relieved in twenty-seven; thirteen cases became pregnant after the operation; of these, only one was examined after delivery, in which case a new laceration had taken place posterior to the line of union of the operation.

The Doctor enthusiastically commends the operation as one redounding with good to the patient and credit to the operator.

A paper by Dr. C. J. Kipp, on traumatic rupture of the drum, was read by title and referred to Committee on Publication.

OFFICERS ELECTED.

President, J. W. Snowden; 1st Vice-President, S. Wickes; 2d Vice-President, P. C. Barker; 3d Vice-President, Joseph Parrish; Corresponding Secretary, Wm. Elmer, Jr.; Recording Secretary, Wm. Pierson, Jr.; Treasurer, W. W. F. Phillips.

Standing Committee, C. J. Kipp, S. S. Clark, and E. J. Marsh.

Delegates to American Medical Association, B. A. Watson, James Green, George Bayles, W. G. Taylor, J. E. Arrowsmith, A. W. Rogers, J. M. Woolverton, H. C. Clark, J. Johnson, C. Shepard, W. H. McGee, J. A. Ayres, T. L. Jamieson, H. Vanderveer, Wm. Elmer.

Delegates to Medical Society of Rhode Island, H. H. James, C. H. Sproul.

To Medical Society of Pennsylvania, W. W. F. Phillips, H. M. Weeks, T. R. Varick.

To Medical Society of Connecticut, D. C. English, D. M'Lean Forman, H. G. Buckingham.

To Medical Society of Massachusetts, C. F. Stillman, D. A. Currie, A. C. Hunt.

It was voted that the next annual meeting be

held at Atlantic City. That the annual assessment be one dollar and a half per capita. The next meeting will be held on the second day in June, 1883. Dr. George Bayles was appointed essayist.

Drs. James, Halsey, Rankin, Currie and Clark, were appointed a committee to investigate when, and of whom, good, reliable and pure vaccine virus may be obtained.

The following, offered by Dr. J. H. Pennington, was adopted:—

Resolved, That the delegates from this Society to the American Medical Association be instructed to resist any effort to alter the Code of Ethics in such manner as to authorize members of the profession, or any Medical Society in affiliation with this Association, to encourage or permit its members to hold professional intercourse with men who repudiate the scientific principles of medical practice recognized by the said American Medical Association.

The following Committee of Arrangements for the next annual meeting was appointed: H. G. Taylor, J. W. Snowden and F. Gauntt, with power to add to its number.

Adjourned.

Testimonial to Professor Leidy.

The following circular, which explains itself, we are glad to insert, as it does honor to one to whom all honor is due:—

PHILADELPHIA, May 1st, 1882.

There is a widespread feeling that the preeminent services rendered to science by Professor Joseph Leidy are such as to call for a suitable and substantial acknowledgment.

He has held the Chair of Anatomy in the University of Pennsylvania for thirty years; and, in addition, the Professorship of Natural History in Swarthmore College for twelve years.

As an anatomist, the foremost place is conceded to him; and as a scientist his fame is world-wide. His contributions to Natural History have ranked him with such naturalists as Cuvier, Agassiz, Owen, and Huxley.

About to enter his sixtieth year, it is felt that the time has come to provide a testimonial which, while expressing the admiration of those who unite in it, for his disinterested and self-sacrificing devotion to science, will relieve him from some elementary teaching and enable him to devote himself hereafter to those fields of profound investigation in which he is unrivaled. This is the more necessary because the system of education conducted in the Medical Department of the University of Pennsylvania has been so greatly changed as to demand from both teacher and student far greater efforts than formerly. It is intended to still further enlarge and elevate the course, so that it shall compare favorably with the highest instruction in European schools. Such changes involve increased expenditures, and a temporary reduction in the receipts from tuition fees. Consequently it becomes doubly important to secure endowments for those chairs which, like that of anatomy, demand the entire time of their occupants. It is proposed, therefore, that the sum of $100,000 shall be raised, the interest of which shall be annually paid to Prof. Joseph Leidy during his lifetime; and that, after his death, the said income shall be applied in perpetuity to the maintenance of the Joseph Leidy Chair of Anatomy, in the University of Pennsylvania. The names of the contributors will be perpetuated in a suitable manner.

Subscriptions to this fund will not be binding until the amount of $25,000 is secured; although it is hoped they will be paid promptly, as they will be invested immediately and become effective. Subscriptions may be made payable during the present year, or in two annual installments.

Rt. Rev. Wm. Bacon Stevens, S. D. Gross, M.D., A. J. Drexel, Alfred Stillé, M.D., Henry C. Gibson, H. C. Wood, M.D., S. Weir Mitchell, M.D., Spencer F. Baird (Smithsonian Institute), John Welsh, George W. Childs, D. Hayes Agnew, M.D., Rev. John S. Macintosh, Fairman Rogers.

All subscriptions should be sent directly to

WILLIAM PEPPER, M.D,
1811 Spruce street.

The prospect for this fund is reported as very encouraging.

How to Cook Rice.

Rice is becoming a much more popular article of food than heretofore. It is frequently substituted for potatoes at the chief meal of the day, being more nutritious and much more readily digested. At its present cost, it is relatively cheaper than potatoes, oatmeal or grain-grits of any kind. In preparing it only just enough cold water should be poured on to prevent the rice from burning at the bottom of the pot, which should have a close-fitting cover, and with a moderate fire the rice is steamed rather than boiled until it is nearly done; then the cover is taken off, the surplus steam and moisture allowed to escape, and the rice turns out a mass of snow-white kernels, each separate from the other, and as much superior to the usual soggy mass, as a fine mealy potato is superior to the water soaked article.

Vaccine Farms.

The following, which we take from the *National Board of Health Bulletin*, May 7th, 1882, will do much to explain why some vaccine virus does not afford protection. Dr. P. H. Bailhache makes this report: "The so-called 'Maryland Vaccine Farm' is located at Contee's station, on the Washington branch of the Baltimore and Ohio railroad, about 16 miles from Washington. I found a colored woman in charge of the farm-house, who, upon my inquiring for Dr. Register, informed me that he had not been at the farm for some months, and she believed he was in Florida, on account of ill health. I then inquired whether the farm was in operation, and she replied that they had been vaccinating calves all winter. Upon further inquiry, I learned that a colored man came down from Baltimore, to vaccinate such stock as could be hired for that purpose, from time to time (the woman said he was the Doctor's driver); that another colored man assisted in the work: that in a short time, ranging from a week to ten days, the 'Doctor's man'

returned to the farm and collected the virus, and that no doctor had been present at any of these operations for some time past. I visited the stable, an ordinary farm stable, which was large and well located, but the accumulation of manure in the rear of the building was very offensive. There was no stock in the stable, but running at large was a young calf, whose unprotected scarifications gave evidence of the recent operations of the vaccinators. Upon making inquiry at Baltimore, I learned that this farm is a private enterprise, and has never been a State institution, or under State supervision of any kind. Its owner was, until quite recently, State agent for furnishing vaccine, and I understand still advertises the article for sale."

Myopia in France.

It is stated in the report of the committee which was appointed some time ago by the French Government to inquire into the prevalence of short-sightedness among the youths at the great Government schools in France, that the cause of the infirmity is to be found in the fact that the school books are printed in type which is too finely cut, and further, that the custom of printing upon white paper is still more hurtful. They recommend, therefore, that the authorities should consider the advisability of substituting thicker characters in the books, and also printing in white letters upon tinted paper.

Burning of the Hygienic Exhibition at Berlin

The Grand Hygienic Exhibition of Berlin, which was to have opened on May 15th, was totally destroyed by fire, May 12th. The exhibits were very fine, and comprised a varied assortment of all known sanitary appliances. The buildings and contents were reduced to ashes.

Items.

—The Professorship of Anatomy in the Harvard Medical School has had but three incumbents in the century of its existence—Dr. John Warren, Dr. John Collins Warren, and Dr. Oliver Wendell Holmes.

OBITUARY NOTICE.

SIR JOHN ROSE CORMACK, M.D.F.R.C P., F.R.S.E.

This distinguished gentleman died in Paris, May 13th, from chronic disease of the prostate and bladder. Born March 1st, 1815, he graduated in medicine from the University of Edinburgh in 1837. His special aptitude for editorial work caused him to turn his energies in that direction, and in 1841 he established the *Edinburgh Monthly Journal of Medical Science*, now well known as the *Edinburgh Medical Journal* Four of the volumes of the New Sydenham Society's translation of Trousseau's *Lectures on Clinical Medicine* were written by him. In 1869 he removed to Paris and began the practice of medicine there, graduating from the University of France in 1870. On the approach of the German Army to Paris, in 1870, Dr. Cormack dismissed several of his family to England, and, with his wife, one son—the late Dr. J. R. Baillie Cormack—and one daughter, remained throughout the siege, during which he rendered eminent service, not only to the wounded, both on the field and in the ambulances, but also as one of the committee formed for the purpose of affording relief to the distressed British residents—an object in which much valuable aid was rendered by the liberal generosity of Sir Richard Wallace. During the terrible scenes of the Commune he remained at his post, affording professional aid to the wounded of both sides, some of whom he received in his house in the Rue d'Aguesseau, while others were placed in a house in the vicinity, occupied as a hospital. After the restoration of peace, his services to the French and to his countrymen were recognized, by the Governments of both countries. In 1871 the French Government made him a chevalier of the Legion of Honor; and in 1872 Her Majesty the Queen conferred knighthood on him. In the letter informing him of his enrollment as a member of the Legion of Honor, M. Jules Favre, the Minister of Foreign Affairs, wrote to him: "For the devotion with which you have cared for the French wounded and dying, whom you have sought on the field of battle, and so faithfully attended in the British Ambulance, France is grateful to you." When the Hertford British Hospital was established in Paris, through the munificence of Sir Richard Wallace, Sir John Rose Cormack was appointed one of the physicians, and held office up to the time of his death. From 1871 to the present time he had a considerable amount of practice, and was held in high regard both by his patients and by his English and French professional colleagues. In 1872, he was elected a Fellow of the Royal College of Physicians of London.

QUERIES AND REPLIES.

J. N. R. is informed by a very large number of our readers that they have known of instances where twins have grown to maturity and have both had families.

T. C. W. would like to have a formula for the use of chrysophanic acid, as a lotion in eczema.

J. W. C. desires to know if any of our readers can furnish him with a sure plan by which a chill can be averted or broken up without the use of quinine or any preparation of cinchona.

N. G.—The authority from which we noted Billroth's Anæsthetic Mixture did not state the point you desire, but we should presume that it is made by measure.

MARRIAGES.

LEAL—AYRES.—On Thursday, May 4th, at St. Luke's P. E. Church, Brooklyn, by Rev. Geo. R. Van Dewater, Malcolm Leal, M.D., of New York City, and Princess K., daughter of Mrs. M. A. Ayres, of Ithaca, N. Y.

WILLITS—McVEIGH.—On Thursday, April 20th, 1882, by the Rev. William V. Kelly, of Brooklyn, assisted by the Rev. A. A. Willits, D.D., Charles H. Willits, M.D., and Clara N. McVeigh, grand-daughter of the late John Whiteman.

ZERNS—COON—April 26th, 1882, at the First Presbyterian Church, Watertown, N. Y., by the Rev. S. A. Hayt, William M. Zerns, M.D., and Anna J., eldest daughter of E. S. Coon, of Watertown.

Compound Chlorate of Potash Lozenges.

This is a new form of combining the well known remedies Chlorate and Bromide of Potash, Tincture Chloride of Iron, and Extract Glycyrrhiza, which has been used with great success for many years, in Acute Affections of the Throat and Bronchial Tubes, as well as in Diphtheria.

These Lozenges are especially useful with children, inasmuch as they are much more palatable than the mixture in the liquid form, and furthermore the Iron in them does not discolor or affect the teeth.

One Lozenge contains 3 grs. each of Chlorate and Bromide of Potash and Extract Glycyrrhiza and 3 drops Tincture Chloride of Iron.

See article of Dr. Carl Seiler, on the New Throat Lozenge, in this Journal, of October 2d, 1880.

EPIDEMIC DYSENTERY,

AS IT MANIFESTED ITSELF IN TRENTON AND A PORTION OF GIBSON COUNTY, TENN., IN THE FALL OF 1881. ITS HISTORY AND ETIOLOGY.

BY T. J. HAPPEL, M.D.

Read before the Medical Society of Tennessee, April 10th, 1882.

(*Concluded from page* 648).

It is true, that Cases Nos. 1, 2, 3, 6, 7 and 8, of the fatal series, might possibly, of an ordinary year, have been attributed to malaria chiefly, but those neighborhoods had had, during the year, so far as I can ascertain, scarcely any ordinary manifestations of the baneful influences of malaria.

In two of the cases, Nos. 2 and 3, the drinking water might have aided in developing the disease, but that could not have been the sole, or even chief, cause, as we would have reasonably expected the adult members of the family, or at least some of them, to have developed the same trouble, which was not the case.

A few cases, my own included, might have resulted from imprudent eating, but by far the larger number of those affected were as prudent in their eating as usual.

The epidemic cannot be accounted for upon the theory of contagion, for although, in many cases, several members of the same family suffered, often in succession, yet neighbors and visitors escaped, though frequently in contact with the disease; and further, cases of the disease occurred simultaneously at too many different points, in persons who had not come in contact with the disease or each other, to give any weight to the idea of contagion.

Case No. 1 was visited by a large number of friends, none of whom contracted the disease.

We would also conclude that no other local or endemic causes existed to give rise, *per se*, to the disease, for there have been, as already stated, only a few sporadic cases presenting themselves, for years, in this city.

Nor can the idea that epidemic dysentery is essentially a filth disease be sustained by any of the facts in this outbreak of the disease.

In 1874 we had a longer drought, but different in many essentials from this one of 1881, but no dysentery resulted.

And, again, were it a "filth disease," due to the concentration of surface decomposition and its conveyance into our water supplies, and from them into our systems, dry seasons ought to produce dysentery, and the disease ought to be epidemic, or the number of cases constantly on the increase in the larger cities; but the reverse of this is true.

Epidemic dysentery, and, to a great extent, sporadic dysentery, has almost disappeared from London (see Watson's Practice of Physic), Philadelphia and New York.

I might cite other facts, but am consuming too much time.

I do not deny that malaria aids very materially in putting the system into such a condition that the disease may occasionally occur, but in addition to this as a first cause, or rather, *one* factor, and errors of diet, exposure to cold, etc., as a *second* factor, there is yet needed *another something*, a "TERTIUM QUID," to bring about, in con-

junction with the other causes, an epidemic of dysentery. Without it only sporadic cases occur.

This "tertium quid" I claim existed and is found in the peculiar atmospheric conditions which were present during September and October, 1881, and that the only solution presenting itself for so widespread an epidemic was and is, *the influence of the high and variable temperature and the meteorological changes, upon those exposing themselves to them.*

From July 1st to the middle of September there had fallen scarcely half an inch of rain in all. The weather had been hot and dry. The ponds of stagnant water evaporated rapidly, so that by August 1st the decay of vegetable matter ceased.

After this long drought, we had a few light rain falls early in September, and then on September 15th a good rain. After a few cool days the hot term took a new lease upon life. Every one became relaxed and enervated. The physical man was soon in a good condition to take on disease of any kind. Supervening upon days of this kind came cool nights; especially were the thermometric variations great toward daylight. The surface capillaries becoming contracted under the stimulus of this cool temperature toward morning, a determination of blood to the internal organs took place. A repetition of this routine day after day, and night after night, soon brought the system in just such a condition that any exciting cause could produce the disease under consideration.

To state my idea a little differently, and to reason upon it a little further:—

The circulation of the abdominal viscera being, so to speak, under the control of the liver, this determination of blood to the internal organs caused a congestion of the liver proportioned to the amount of determination; now, whatever produces a congestion of that organ deranges this portal circulation and produces a general portal congestion, and a frequently recurring portal congestion was, of course, followed by as frequent a congestion of the mucous membranes of the rectum and descending colon, as well as that of the balance of the alimentary canal.

The venæ portales being unsupplied by valves, the capillary congestion was most marked in those portions where gravity brought to bear the heaviest forces; hence, was greatest in the mucous lining of the rectum and descending colon.

Now, having stated as briefly as possible my idea of the cause of the epidemic, and its modus operandi, let us study, for a while, the conditions of the atmosphere, with its changes, as shown by the thermometer, barometer and hydrometer.

Having stated, in general terms, the status from July 1st to September 1st, we will begin a more minute examination from September 1st, as, prior to that time but few sporadic cases of the disease occurred.

From September 1st to 10th the average maximum temperature was 93½°; the average temperature at 6 a.m. was 73½°, making an average daily variation of 20°. The maximum temperature was 97°, the minimum 69°, making a variation between the two extremes of 28°. For the five days following the 10th, the average maximum temperature was 72°, the average minimum temperature 63°, making a variation of only 9°; but taking the two extremes, at noon on the 13th, the maximum temperature was 94°, and on the morning of the 12th 56°, thus making the greatest range 38°. On the 15th, as previously stated, a good rain fell, and on the 16th the minimum temperature was 58°, and the maximum 71°, a variation of 13°. On the 17th the maximum temperature was 74°, the minimum 52°, a variation of 22°. From the 17th to the 21st the average minimum temperature was 59°, the average maximum 78°, the average variation 19°. The lowest temperature was 52°, on the 17th, and the highest 84°, on the 20th; thus making the greatest variation 32°. From the 17th to the 22d the morning temperature gradually increased to 66°, while the noon temperature rose to 86° on the last named day.

From the 22d to the 26th, inclusive, the 6 A.M. temperature gradually increased from 66° to 74°, while the noon temperature went to 90° on the 25th, making a difference of 38° between the minimum and maximum temperature in eight days. On the 26th the maximum temperature dropped to 74°, to be followed at once by a daily increase of from 3° to 5° in maximum temperature to the 29th, reaching 86°, giving a variation of 21° between the two extremes of that day.

The barometric changes from September 1st to 13th were very slight, and with the exceptions of the 3d and 4th, not falling below 30, but at the same time the hygrometric variations were decided; especially was this the case on the 4th, when the humidity at 6 A.M. was 88.6, while at 2 P.M. it was only 37.4, a difference of 51.2.

The 14th and 15th were days of considerable barometric changes, with rain on the latter day, followed by a rising barometer and increasing temperature on the 16th. On the 17th a stationary barometer, but humidity varying from 91, at

6 A.M., to 27 at 2 P.M., being a change of 64. On the 26th a falling barometer and increasing humidity, the average being 83.

October opened with a morning temperature of 70°, rising to 84° on the same day, and to 88° on the next; then to fall to 56° on the evening of the 5th, giving a variation of 32° in four days, converting a late fall month into one of midsummer heat.

On the 6th the morning temperature was 54°, and at midday 75, making a variation of 21° in six hours. On the 10th we find the morning temperature 59°, and on the 11th 55°, with a maximum on the latter day of 80°, making the range 25° for that day. The 12th, 13th, 14th, 15th, and 16th are noted for their great range of temperature, rising on the latter day to 85°, to drop on the 17th, in the evening, to 54°, and on the morning of the 21st to 43°, showing a difference of 40° in five days, with a variation of 18° the next day. From the 23d to the end of the month the temperature was much more uniform, the greatest variation in the daily mean temperature being 6°. The changes of the barometer were slight in October, to the 23d, and from that time to the end of the month very variable and uniformly low.

The hygrometer showed but slight changes to the 12th, and then they became marked, being 24 on the 13th, 31 on the 14th, 42 on the 15th, 38 on the 16th, attaining a maximum variation on the 20th; on that day being 88½ at 6 A.M, and 39 at 2 P.M.

From that time onward the variations in humidity were not so great till the 26th, when we find the variations 51, with a decrease in variation until the end of the month.

November opened with a variation of 21° between the extremes of temperature, to be reduced the next day to 19°, with a further decline in the morning temperature on the 4th to 40°, making in four days a difference of 29°, changing from summer's heat to frost on the 4th. From that time on the temperature, though moderately high, continued uniform. November will be remembered as a warm month up to the 20th.

Both the barometer and the hygrometer varied much from the 1st to the 10th of November. The variation between the two extremes was .614 inch, and of the hygrometer 58, with a daily variation on the 1st of 47.

Now, the variations in temperature given have been ascertained by comparing the minimum and maximum temperature, as read from a thermometer not exposed in any way to the direct or indirect rays of the sun. If, then, to the variations already given, we add about 20° increase in heat to which those were exposed who were unprotected from the midday's sun, the gap between the daily minimum and maximum temperature becomes enormous, reaching in some cases to upward of 50°.

With this amount of daily variation, and its consequent effects upon the human system, I see no trouble in accounting for the epidemic under consideration.

Let us study a little further, first, the fatal cases already cited, and further facts will be found to warrant the assumption that the "tertium quid" giving rise to the epidemic was the unusual and excessively high and variable temperature.

Of the fifteen fatal cases reported, six were adults, four males and two females, but all of such stations and conditions in life, and following such vocations, except one, as to necessitate an active out-door life, exposed to these decided variations in temperature; four were children, ranging from four to seven years of age, just the age at which it is impossible to restrain a vigorous, active child; four of the remaining ones were old enough to be in and out of doors at all times; and only one was too young to be exposed much.

A majority of the deaths in this series took place from October 1st to the 20th, and several others in the last week in September—the ver time at which the temperature was highest and the atmospheric changes greatest. Then, too, according to my own observations, confirmed by those of Drs. Moore and Bright, the epidemic was most extensive about the same time.

As has already been remarked, the week succeeding the Fair was one of greatest suffering, and by examining the weather statistics given, it will be seen that from October 11th to 25th the changes were great and sudden. Then, too, at this particular date more persons were exposed to those changes than at any other time during the fall.

Frequently those persons who had any distance to travel started early, were then exposed to the cool morning air; at noon were frequently in the direct rays of the sun, and returning through the dust in the evening, were out in the sultry night air.

Again, the large majority of those who escaped any enteric trouble were persons whose vocations were such as to keep them indoors, or whose circumstances in life were such as not to force them to labor and expose themselves.

In conclusion, I do not pretend to claim that

the high and variable temperature and atmospheric changes were *alone* the causes of the disease, but that it was the great predisposing agent, the factor which put the systems of so many in just such a condition that any exciting cause could and did give rise to the epidemic.

Malaria aids, and so does exposure to cold, errors of diet and similar causes, as set forth in our works on diseases; but these, of themselves, can never give rise to an *epidemic* of dysentery.

As already stated, these causes can produce only sporadic cases. Malaria, too, would be a complication, and often a grave one, in epidemic dysentery, and, had it existed as an important factor in the disease of this year, in my opinion, the epidemic would have numbered its victims by the scores.

But let all these minor factors be present, and no high, variable temperature and atmospheric changes present themselves, and you have no *epidemic dysentery;* but let the latter factor, the *tertium quid*, be present, then, almost any one, or, at most, two of the former factors will kindle up the epidemic.

Hospital Reports.

UNIVERSITY OF THE CITY OF NEW YORK.

CLINIC OF J. WILLISTON WRIGHT, M. D.

Professor of Surgery.

Lupus Non-exedens.

Gentlemen:—There is a dearth of material at our clinic to day, but we will present such as we have. The first patient is a man fifty-five years of age, who says that about two years ago he received a slight injury on the side of the nose, which developed into a warty excrescence, at first about the size of a bird shot, but having now extended until it covers a space larger than your thumb nail. On picking off the outer wart like crust there is exposed beneath fungus-like granulations. It has all the appearance of lupus of the nose, a favorite locality for that disease. You will remember that there are two varieties of lupus, one a slow, quiet form, which does not show any marked tendency to ulcerate, or rather to destroy the tissues; consisting of a ragged, rough surface, without any ulceration, whatever, and fringed at the margins with a quantity of small, tubercular-looking bodies, of a red color, and outside of this, adjacent to the margin of the disease, a desquamation of the skin. This form is known as lupus non exedens. The other form is known by the various names of rodent ulcer, lupus exedens, *noli me tangere*, etc. The latter form is characterized by rapid progress, by its tendency to destroy everything which comes in its way—not only the skin, the connective tissue, and the cartilage of the nose, if it happens to be in that portion of the face, but finally even the bones, so that sometimes it produces the most frightful ravages on a man's face, eating out the whole cheek, carrying away the bones which form the floor of the orbit, a good part of the upper jaw, and sometimes allowing the eye itself to drop down into this frightful chasm which has been made by the progress of the disease. It reaches this aggravated stage generally within a very few months.

Very often the two forms seem to be intimately associated with one another. For example, we find here unquestionably an example of the milder variety of the disease known as lupus, but we have no guarantee that, at any time, it may be next week, next month, or next year, this condition may not pass into the other. It seems proper, therefore, to make some effort to relieve the man of this growth while it is in this comparatively harmless condition.

Now, there are two or three ways of dealing with it; we may, for instance, encircle the mass with the point of the knife, and dissect that portion of the skin and connective tissue out. Then we may close up the opening thus made by sliding the integument over a little, doing some plastic surgery, or what would probably be better, inasmuch as we are dealing with a disease which has a certain amount of malignancy about it, to say the least, treat it as an open wound, and allow it to granulate. On the other hand, we can destroy the growth by the use of an escharotic, and this is the treatment which I think is proper to make use of in this particular case. We will simply lift the dry crust which has formed over the disease, scraping it with the scalpel, and then apply, pretty thoroughly, some powerful escharotic; for this purpose one of several different kinds of escharotics may be used. A favorite one with many surgeons is what is known as butter of antimony, which is applied with a little swab, as a piece of cotton wrapped round the end of a stick, or applied with a glass brush, or by other means. Another very good escharotic consists of a saturated solution of chromic acid. This, perhaps, is not as painful as the butter of antimony, and at the same time, I do not think it is as effectual in its results. Another is what is known as Vienna paste. The acid nitrate of mercury is a powerful escharotic, and may be applied in the same way as butter of antimony. There is, however, a particular escharotic which I wish to try the effect of in this case, namely, what is called chlor-acetic acid, which looks in the bottle, as you see, very much like water, but which has very powerful caustic effects. I have found it the best substance that I have used for the treatment of papillary tumors, such as warts, etc. Of course, this substance will produce some sloughing of the tissues. After the application the sore will be treated by a piece of lint spread with the nitrate of mercury ointment, full strength. At the same time the patient will be put upon constitutional treatment, say ten drops, three times a day, of Donovan's solution, that is the iodide of mercury and arsenic; it may also be well to give him some preparation of iron.

If the fungous mass springs up again it will be treated in the same way.

Arthritis.

Our next patient is a man forty-two years old, a peddler by occupation, who slipped and fell on the stairs, in the latter part of January, 1882, striking his left shoulder on the edge of the stairs.

On comparing the shoulders one with the other, you will observe that there is a greater prominence, a protuberance, at the junction of the scapula and acromion process. You will also observe a slight spasmodic contraction or twitching in the triceps muscle. In evidence that there is no dislocation of the humerus, you see we are able, after placing the left hand on the opposite shoulder, to bring the elbow down against the walls of the thorax. Another test for dislocation at the shoulder is to lay a straight surface, as a ruler, against the external condyle of the humerus below, and if possible, the other end against the acromion process above; if there be no dislocation, the round head of the humerus will so project as to make it impossible to bring the upper edge of the ruler against the acromion process, while the edge below lies against the external condyle; but if there be a dislocation of the bone out of the glenoid cavity, in almost any direction, this can be effected. Still another test consists in taking the circumferential measurement of the shoulder, comparing it with the opposite side. It is not as absolute a test as are the others, because the man may be differently developed on the two sides. But when it is remembered that in dislocation there is an increase of about an inch and a half or two inches in the circumference of the shoulder, it becomes a pretty positive test, for it is not likely that a man will be so unequally developed as to make so great a difference. In this case the measurement outside of the prominence on the right side is fifteen inches, while on the left, the affected side, it is only fourteen and three quarters inches. Certainly, then, there is no dislocation. Nor is there any paralysis of the deltoid muscle, for the man is able to lift his hand above his head. You will observe that we are eliminating everything that it may be, and bringing it down to the only thing which it can be; in other words, we are making the diagnosis by exclusion.

The next thing to be considered is, whether there may not be some inflammatory action going on in the joint. When I rotate the bone in the glenoid cavity the patient does not complain of it at all, except when I bring a strain upon the particular prominence before mentioned. So far as the shoulder joint itself is concerned, there seems to be no trouble going on there. There is not only no pain on rotating the humerus, or on pushing it solidly into the socket, but there is no crepitus whatever. Therefore we can be certain there is no erosion here, of the cartilages, nor effusion into the joint.

Then we come to consider the point at which pain seems chiefly to centre, namely, just at the articulation between the acromial end of the clavicle and the acromion itself. Now, we may possibly have fracture of the clavicle here, which gives rise to this prominence; it may be possible to have fracture at so close a point to the articulation. But we find no evidence of this on examination; there has been no callus thrown out, causing any enlargement of such a nature, but there would have been some, even had the bone become very closely and smoothly united. If there were dislocation of the clavicle with the acromion process, either by slipping above or below it, there would be a difference in measurement from the centre of the sternum to the acromion process on the two sides. But here we find the measurements exactly the same. Besides that, if there were dislocation under the acromion, this process would ride up abruptly; or if a dislocation over it, there would be a similar elevation or overriding of the clavicle.

Therefore, gentlemen, we will put this case down as one simply of arthritis, and I think it very doubtful whether the injury which the patient sustained in January is wholly responsible for it. It may be, but I think it quite as likely that this inflammatory action about the joint, which has thickened the cartilaginous surfaces, and probably also the synovial membrane, has another origin, probably in rheumatism. The injury may have been the starting point, the exciting cause, but not the predisposing cause.

The treatment will consist in the administration of the iodide of potassium, five or ten-grain doses three times a day, and the application in this locality of a series of small fly blisters. Put on one to-day or to-night, perhaps three inches square, and after it has been on about eight hours puncture the vesication, letting the water out, and dress it with simple cerate, or combined with a little morphine, to make it more anodyne. Continue so to dress it until the blister heals, and if then, after two or three days, the pain and tenderness do not subside, put on another, and so repeat the process, if necessary, until the patient has had six or more vesications. If he be faithful in this treatment, I think that after awhile the pain will subside, and probably considerable absorption and decrease in the enlargement will take place.

Inguinal Hernia.

This man is employed about machinery, and some time ago noticed a tumor in the inguinal region, which has been getting larger. On examining this tumor we find that it does not extend down into the scrotum; that it is tympanitic on percussion; that it has a distinct impulse when he coughs. I will answer my own question as to whether this hernia is direct or indirect, by saying that it is a question difficult to decide in the living subject like this, and it is for this reason that, in a strangulated hernia, we cut directly upward, for we know not on which side of the epigastric artery the gut lies. In an old hernia like this, if it be through the internal abdominal ring, the two rings will probably be so closely drawn together, by the weight of the hernial mass, as to make it very difficult to decide whether it be a direct or indirect hernia. In the case of this patient the hernia is very easily reduced, and goes back with a very distinct gurgling noise. It can be made to come and go at pleasure as he lies down, and coughs. Invaginating the scrotum, and introducing my finger into the external ring, I find it greatly enlarged; this can be felt easily, also, without

invaginating the scrotum, and the hernia seems to have come directly through Hesselbach's triangle.

This man needs a good, strong truss, with a stiff spring, and a rubber water bag or air pad, so as to thoroughly prevent a protrusion of the hernia. He says he is too poor to purchase one.

He will be supplied with one free, by going to the Institution for the Crippled and Ruptured, Lexington avenue and Forty second street but it is not to be supposed they can afford to give away trusses of the highest quality, such as this man ought to wear.

Medical Societies.

PHILADELPHIA COLLEGE OF PHYSICIANS.

Remarkable Case of Sacculated or of Cirsoid Aneurism of the Second Interosseous Branch of the Deep Palmar Arch, Treated by Excision; with Exhibition of the Specimen.

BY JOHN B. ROBERTS, M.D.,

Lecturer on Anatomy and on Operative Surgery in the Philadelphia School of Anatomy.

Read May 3, 1882.

The specimen which I exhibit this evening, and its accompanying history, are interesting, I think, because of the extreme rarity of the condition. I know of no similar case reported; but I have not had an opportunity to search for such in medical literature, because the operation was performed only a few hours ago. The specimen is fresh, and is exhibited now before the appearances have been changed by any preservative fluid.

Dr. Charles H. Thomas requested me, a few days ago, to assist him, at an early date, in operating upon a tumor of the hand in a boy, aged sixteen years. From his earliest childhood he had been under Dr. Thomas's observation, and had had a small elongated tumor upon the *dorsal* surface of the first phalanx of the left ring-finger, while in the *palm*, at the junction of the bases of the middle and ring-fingers, was a larger swelling. These were considered masses of dilated veins, as they had a spongy feel, and at times showed a bluish color. There was no very definite connecting band of swelling between the dorsal and palmar enlargements. No special pain was experienced, unless the parts were struck, and no marked growth occurred. Hence the child's mother was advised to have nothing done. As the boy grew, the hand and tumor increased, but held the same relative proportions. When the boy began work in a machine shop, the skin became thickened and soiled, and the bluish tint was no longer discernible.

About two months or less ago the growths seemed to enlarge and to be accompanied by considerable pain, and Dr. Thomas advised the use of a compress in the palm and a bandage around the finger. This the boy wore at nights, and usually from Saturday to Monday morning, when he returned to his work. Recently there was noticed pulsation in the palmar tumor and a lobulated feel; and Dr. Thomas feared that an arterial aneurism existed.

When I examined the boy last evening, I found on the back of the third finger a hard, fibrous-like tumor, as large as a watermelon seed, with the long diameter corresponding to the length of the phalanx. In the palm was an illy defined swelling covered with thick skin, very sensitive to pressure, and occupying about the area of a silver half dollar. No swelling was evident connecting the two tumors. On the ulnar side of the palmar mass moderately distinct pulsation could be felt, which quickly stopped when the radial artery was compressed at the wrist, but merely decreased in force when the ulnar was pressed upon with the fingers. No pulsation was felt in the dorsal tumor.

The boy had severe pain even when no pressure was made upon the growth in the palm.

I gave it as my opinion that the growth was an arterial angeioma connected with the second interosseous branch of the deep palmar arch, having anastomoses with the digital branches of the ulnar artery. Dr. Thomas considered it possibly this, but probably a sacculated aneurism. His diagnosis has proved to be the more correct.

It was determined to employ the Esmarch elastic bandage, and to make a free incision over the tumor and dissect it out, whether it be angeioma or aneurism. As Dr. Thomas was disabled by a painful boil on his right hand, he requested me to operate. The boy was etherized and the elastic bandage applied.

I made an incision from a point a little in front of the superficial palmar arch to the commissure of the fingers, and came upon a mass of fat and small vessels, in the centre of which was a bluish nodule, resembling larger vessels containing blood not driven out by the elastic bandage. Keeping close to the skin, and going down to the sheaths of the flexor tendons, I dissected the mass free. Lying alongside of the palmar interosseous muscle going to the ring-finger (2d interosseous) we saw a comparatively large vessel which seemed to be the main feeder of the mass. I then extended my incision, making a straight cut along the side of the ring finger, dissected up the skin, and enucleated the hard nodule lying on the back of the first phalanx. This seemed connected with the other mass by some fibres or small vessels, and both were removed as one piece. The wound was then plugged with dry muslin, to stop the general oozing that occurred after removal of the bandage, and a tight bandage applied. No ligatures were required, because my incisions were made at a distance from the tumor.

Dissection of the palmar mass showed that I had removed a small body, about three-quarters of an inch in diameter, containing clotted blood, and surrounded by adipose tissue and nerves. Small collapsed vessels in large numbers may, perhaps, be found in this adipose tissue, by microscopic examination. Only a few larger ones were recognizable by ocular inspection, because of the absence of blood from the interior. The tumor, as is seen on the plate, consists of three lobules of rather unequal size, arranged somewhat as a trefoil. The largest one of them, which has been punctured, allows the escape of soft clot; this sac is about one-half an inch in

diameter. The three sacs seem to be separate, because the head of a pin introduced into one does not pass into the others. The two smaller sacs or lobules are hard, as if the clot was old. One has been laid open, and shows a white centre, or nucleus, of cartilaginous consistence, surrounded by a layer of red clot. On the surface of this three-lobed tumor runs a nerve, which probably was the seat of pain from pressure, and parallel to it a small artery. Both of these become lost in the mass, at the upper end of the tumor, which was thought to contain the main supply of the aneurism, and around which a string was tied and left for identification.

The tumor from the back of the finger is hard, and on section shows an irregularly colored red surface. I believe the tumors, therefore, to be small sacculated aneurisms, evidently allied to or identical with the variety called cirsoid aneurism. The one on the back of the finger and the two smaller lobules in the palm are undergoing cure by coagulation, induced in the dorsal one, undoubtedly, by the pressure from the bandage used at intervals during the last six weeks or two months.

If the diagnosis had been more certain as to aneurism, I believe that digital compression of radial and ulnar arteries, or the use of an Esmarch elsatic bandage to the forearm, would have been the proper treatment before excision was attempted.

The early period of life (about three years) at which the trouble was noticed primarily renders it probable that the aneurisms were not originally traumatic. It is possible, I suppose, that the vessels of an arterial angeioma may have become so dilated as to resemble these multiple aneurisms.

The similarity to cirsoid aneurism is certainly very great, though there are some points which differ somewhat from the usual clinical history of these growths.

After the reading of the preceding paper:

Dr. W. W. Keen called attention to the danger of using coagulating agents in such cases, and spoke of a case of traumatic origin he had seen in consultation, in which a few drops of Monsell's solution had been injected into the aneurismal sac, and gangrene had followed, necessitating amputation of the hand. He thought compression of the radial and ulnar arteries would probably have accomplished a cure, and the risks of an operation would have been avoided. With regard to the small tumor on the dorsal surface of the ring finger, he thought it unlikely to be an aneurism. Nothing short of a microscopical examination would determine its nature.

Chloroform Mortality.

The *Lancet*, February 11th, 1882, editorially says:—

The number of deaths at present occurring from the administration of chloroform is so startling, that it is arresting public not less than professional attention. One of these fatalities occurred at Malvern Wells, and is a fair specimen of many more. The patient, Charles Holmes, a man fifty-one years of age, consulted Mr. Haynes for dislocation of the shoulder. Mr. Haynes tried the usual modes of practice for reducing the dislocation without anæsthesia, but did not succeed, and, failing, determined to reduce under chloroform. He took every reasonable precaution before carrying out this intention. The examination of the heart gave no indication of disease, and there was no obvious reason why the narcotic should not be employed. It was also used with due care, but during the second degree of muscular excitement the patient became collapsed, and rapidly died. The post-mortem, conducted by Mr. H. J. Brown, of Worcester, revealed "long-standing structural disease," fatty degenerative change, we presume, of all the vital organs; so that "the man might have died at any moment." The class of case here presented is typical. There is a large population of this kind, a population of men and women, but of men especially, who, without presenting, even to skilled observation, their precise state, are liable to die at any moment. They die from slight mental shocks; they die from comparatively slight physical shocks; they die under efforts to run or climb; they often die in attempting to catch the train against time; they die in the most ready manner under certain of the anæsthetics. It is probable they are in danger under any of the anæsthetics which are as yet known, but it is certain that they are in great danger under every one of the class that belongs to the chlorine family. The chlorine, which really has nothing to do with the production of the anæsthesia, for that depends on the organic radical with which it is in combination, is the cause of the danger. It acts as an irritant. It produces sudden contraction of arterial fibre, arterial shock, by which the course of blood through the pulmonary and systemic circuits is impeded, and the feeble heart, unable to meet the difficulty, is arrested in its action during the second degree of anæsthetic sleep. The practical lessons to be remembered on this very solemn subject are always deserving of mention. In the first place, there can be no doubt that when any suspicion exists that life is not at its best, and that the heart is feeble, ether should take the place of chloroform. Ether relaxes, and for a case of dislocation, is singularly superior to chloroform. If the administration of ether is, for any reason, not practicable in the class of cases to which we refer, then the chloroform administration should be preceded by a full dose of some agent that has the relaxing effect of ether, and that agent we have at hand in ethylic alcohol. From one to two ounces of pure alcohol —specific gravity .830—is a valuable preliminary,

and should be given, diluted in eight ounces of water, from five to ten minutes before the inhalation of the narcotic is commenced. With these precautions. the dangers of anæsthesia may be greatly reduced; and they ought to be rigidly followed until the time comes when science shall give to us a new agent that, with all the facilities of chloroform, in respect of convenient and ready administration, shall combine the safety, with something more than safety, of anhydrous ether. In Mr. Haynes' case the coroner very properly asked Dr. Pike, of Malvern, whether, under the same circumstances, he would have used chloroform. and, receiving an affirmative reply, recalled Mr. Brown, to question him as to the propriety of a surgeon acting single handed in cases of operation. Mr. Brown answered that in country districts it was impossible for the surgeon to always provide another surgeon to administer; and this is the fact. It should, however, render more scrupulous the care with which the anæsthetic is selected.

Cirrhosis of Liver—Paracentesis—Recovery.

The following case, reported in the *Lancet* by Dr. R. A. D. Lithgow, possesses more than passing interest:—

A retired farmer, in good circumstances, aged between fifty and sixty, of full habit and lymphatic temperament, had for many years daily consumed a large quantity of alcohol, principally whisky and sherry; although not perhaps a drunkard in the usual acceptation of the term, he was nevertheless a deliberate and persistent drinker of ardent spirits in considerable quantities, from day to day. His general health had hitherto been fairly good, and with the exception of occasional "bilious attacks," there was seldom anything the matter with him.

On November 1st, 1877, previous to which the patient had been suffering from dyspepsia associated with symptoms of gastro enteric catarrh, he was seized with violent sickness, pain in the region of the liver—evidently the result of perihepatitis—and jaundice. Effervescing salines and podophyllin pills were ordered, also the local application of poultices and fomentations, and these gave him temporary relief, although the jaundice persisted, and there were physical signs of hepatic enlargement. On November 8th I called in my friend, Dr. T. J. Walker, of Peterborough, in consultation, and we concurred in regarding the case as one of incipient cirrhosis of the liver. Appropriate treatment by medicines and regimen was, as far as possible, adopted and enforced until the beginning of May, 1878; but in the meantime the chronic interstitial inflammation progressed, with accompanying symptoms of portal obstruction, and ultimately ascites with general anasarca. The patient finally became so cumbrous and helpless—the breathing becoming daily more difficult—that the question of tapping could not be much further delayed. Accordingly, as a preliminary, his legs were freely scarified on the 7th, and again on the 9th of December, 1877; and by these means his general condition was considerably relieved. The fluid, however, increased rapidly, and paracentesis abdominis was for the first time performed on December 24th, 1877. He was again tapped on January 16th, 1878, February 1st, 15th, and 27th, as much time as possible having been allowed to elapse between each operation. During the month of February he was ordered a mixture containing balsam of copaiba, and afterwards of oil of sandal, but these producing sickness, they were discontinued. Paracentesis was again performed on March 12th, 1878; also on March 25th, April 9th, April 20th, May 2d, May 16th, and, for the twelfth time, on May 30th, 1878. I am almost positive that the patient was tapped thirteen times, but as I find no note to this effect I think it best to adhere only to undoubted facts. On May 2d, 1878, the patient was ordered the following mixture, which he continued to take almost up to the time of his recovery: Half a drachm of iodide of potassium, one drachm of the tincture of digitalis, half a drachm of the tincture of capsicum, three drachms of simple syrup, to six ounces of water; one-sixth part to be taken every four hours. From the beginning of June, 1878—almost immediately after his being tapped for the twelfth (thirteenth?) time—the patient showed symptoms of gradual amendment, and on the 28th August, 1878, he was so far recovered as to be able to go to Brighton, from which he returned almost quite well, in a few weeks.

Remarks.—The symptoms were at one time complicated by an attack of concurrent subacute bronchitis, which fortunately yielded to appropriate treatment. As the patient persisted in having some stimulant, especially during his convalescence, he was ordered a pint bottle of champagne daily. During the progress of the case, the diet, for the most part, consisted of milk and beef tea, given systematically, a few teaspoonfuls of brandy being occasionally, but as seldom as possible, administered in milk. The kidneys acted well throughout, and the patient suffered little inconvenience from the tappings, which were performed as he lay upon the edge of the bed.

January, 1882. I have just heard that, the patient having resumed his intemperate habits, active mischief has once more developed itself in the liver, after the lapse of nearly three years and a half, during which he enjoyed fair health.

Congenital Cardiac Disease.

At a recent meeting of the Pathological Society of London (*Medical Times and Gazette*) Dr. Hadden related a case of congenital cardiac disease. The patient was a female child, four months old, and was under the care of Dr. Bristowe at St. Thomas' Hospital. On admission, the face was pale, the hands and lips livid, the chest expanded badly: the respiration was 66. Lung resonance in front was impaired, but breathing was vesicular. At the bases there was impaired resonance, with crepitation and rhonchi. No cardiac murmur was heard; no mention was made of heart's dullness in the notes. Improvement followed the next day. On the third day there was dullness over the left lung anteriorly, and scattered dullness at both bases, with crepitation and rhonchi. Before death the respiration was 96, and the temperature 101°. Post mortem,

the heart weighed four ounces, the average weight at patient's age being rather less than one ounce. The septum between the ventricles was imperfect above, admitting the middle finger easily. The right ventricle was much hypertrophied, a quarter of an inch thick in some parts; the cavity was dilated at the right apex-wall, half an inch transversely. The muscular papillæ were much hypertrophied; the left ventricle was much hypertrophied; the foramen ovale and ductus arteriosus, although allowing the entry of a small probe, were practically closed. The pulmonary artery was large, the aorta inversely small. Both arose from the ventricle in the usual way. Both the lower lobes of the lungs were collapsed; the upper lobes were relaxed and crepitant; the bronchi were dilated. The nature of the case was not suspected during life, perhaps because the pulmonary trouble obscured physical signs referable to the heart. It is worthy of note that the heart weighed nearly five times the usual amount.

Reviews and Book Notices.

NOTES ON CURRENT MEDICAL LITERATURE.

——"Electricity in Medicine and Surgery, with Cases to Illustrate." By John J. Caldwell, M.D., of Baltimore.

——We have received the announcement of the Woman's Medical College of Baltimore, for the session of 1882–83.

——We have received the annual report of the Central Dispensary and Emergency Hospital of the District of Columbia.

——"Genius Resistless;" a pindaric ode, in tribute to Jenner and Pasteur. By J. J. Caldwell, M.D., of Baltimore. This interesting little ode we have received, with the compliments of the author.

BOOK NOTICES.

Diseases of the Ear in Children. By Anton Von Trœltsch, M.D., Professor in the University of Würzburg. Translated by J. Orne Green, A.M., M.D., Aural Surgeon, Boston City Hospital, etc. pp. 165. New York: William Wood & Co., 1882.

The author of this volume makes the statement that "in childhood, apart from a few weeks immediately following birth, an unusually strong predisposition to diseases of the middle ear exists, owing, on the one hand, to the double influence of the peculiar morphological relations of the ear and the pharynx; and on the other hand, to the diseases and conditions of life to which the child is frequently exposed." If such be the case, it would be well for all physicians to have some knowledge of the nature and treatment of diseases of the ear. The literature on this branch is rather meagre, more so than on any other branch of medicine; therefore we welcome most cheerfully this little volume before us, and commend it highly to all.

A Practical Treatise on Diseases of the Skin. By Louis A. Duhring, M.D., Professor of Diseases of the Skin in the University of Pennsylvania, Dermatologist to the Philadelphia Hospital, etc., etc. Third edition, revised and enlarged. pp. 685. Philadelphia: J. B. Lippincott & Co. 1882.

An extended notice of this book is uncalled for. It is already well known to the profession, and wherever known, it is considered as undoubtedly and unquestionably *the* book on diseases of the skin. Dr. Duhring is everywhere recognized as an earnest and intelligent gentleman, who has devoted his time religiously to the elucidation of the nature and treatment of this most obstinate and intractable class of diseases; and this volume embodies the results of his great research. It is only necessary for us to note the issue of this third edition, thoroughly revised and fully up to date.

The Student's Manual of Histology, for the Use of Students, Practitioners and Microscopists. By Charles H. Stowell, M.D., Assistant Professor of Histology and Microscopy in the University of Michigan. pp. 290. Detroit: George S. Davis, 1882.

This is a very excellently illustrated manual, containing one hundred and ninety-two engravings. Histology is making such rapid progress that it is necessary for one to keep constantly reading and studying, else he will be found behind the age. Dr. Stowell has written a very good book; it is couched in simple, intelligible language, and is an excellent exposition of the position of histology to-day, so far as it can be expressed in so small a work.

Chronic Bronchitis—Its Forms and Treatment. By J. Milner Fothergill, M.D. Edin. pp. 160. New York: G. P. Putnam's Sons. 1882.

Dr. Fothergill is a voluminous and always an agreeable writer. This book is no exception to the rule. This author seems to possess the rare and happy faculty of writing what he wishes to teach in such a style as to make it not only valuable to the physician, but also, clear, plain, intelligible reading. So many excellent works lack this pleasantry of style, that it seems almost like an oasis in the desert when we pick up one of Dr. Fothergill's works. We can heartily commend this book, which contains much valuable advice.

THE

Medical and Surgical Reporter,

A WEEKLY JOURNAL,

Issued every Saturday.

D. G. BRINTON, M.D., EDITOR.

The terms of subscription to the serial publications of this office are as follows, payable in advance:—

Med. and Surg. Reporter (weekly), a year,	$5.00
Half-Yearly Compendium of Med. Science,	2.50
Reporter and Compendium, - - -	7.00
Physician's Daily Pocket Record, - -	1.50
Reporter and Pocket Record, - - -	6.25
Reporter, Comp. and Pocket Record, - -	8.25

For advertising terms address the office.

Marriages, Deaths, and Personals are inserted free of charge.

All letters should be addressed, and all checks and postal orders drawn to order of

PHILADELPHIA, PA.

THE LAST SIX MONTHS.

We again present our readers with a full index of the contents of the REPORTER for the last six months. It presents an even more varied and extensive range of subjects than usual. The activity of the medical world is unflagging, and we can justly anticipate great and beneficent results in the near future, as the fruit of this intellectual activity.

What particularly characterizes modern science is the perfection of its method. The laws of phenomena are sufficiently understood to act as secure grounds for the investigator of the still hidden secrets of nature and man. Those who persist in blinding themselves to these laws, and deny those methods, will undoubtedly find themselves attacking an invincible opponent. It behooves those who see more clearly, or who are more honest to their perceptions, to repudiate and shun such pseudo-scientists.

The productions of the medical press have been regularly brought to the notice of our readers. They have, perhaps, not contained so many new productions of conspicuous merit as in some previous semesters; but the supply shows that the demand in the profession is greatest for the best class of works, especially for treatises on special subjects by those thoroughly conversant with them.

The proceedings of the Societies have been reported at considerable length. They indicate, better than any other kind of reading, what are the living, moving ideas of the day, and deserve attentive perusal.

On the whole, we believe we can say that a review of the numbers for the six months will convince any one that the art of medicine shares in full the progressive spirit which characterizes the most of the aims of human intelligence in the present day.

THE AGE OF BACILLI.

The history of the Science of Medicine teaches in no uncertain terms the fact that, from the beginning of the world of medicine, our profession has been at different times dominated and influenced by certain theories, all of which have seemed at the time to possess sufficient reality to cause them to influence and direct the whole tendency of medical research and clinical treatment into channels in accord with their teachings. The humoral theory of disease, at one time accepted by the greatest medical teachers as the source of all our ills, is only one out of many illustrations that could be adduced to substantiate this proposition.

All the various theories that have been presented from time immemorial, have had for their basis the fundamental idea of the presence in the body of some foreign element or elements, of some pathological constituent of the human body, which, being abnormal and inimical to healthy life, was the direct cause of disordered or morbid manifestations, thereby producing a diseased condition of the organism.

In this general age of progress, our profession is not behind the times. We have now our "*new departure;*" we are now dominated by a new idea concerning the causative agency of disease, and one that seems to possess more rational grounds for acceptance than any that have gone before.

Commencing really with the experiments and experience of JENNER, this idea of *bacilli* has been gradually engrafting itself upon the minds of medical investigators, until to-day we have it claimed that several of the most serious and most prevalent diseases known to men are produced by the presence of bacilli in the body.

From Italy we have the *bacillus malariæ*, of TOMMASI CRUDELLI; from Germany the *bacillus typhosus*, of KLEBS; from America the *bacillus* of diphtheria, of WOOD & FORMAD; from France the *bacillus anthracis*, of PASTEUR, and lastly, from Berlin the *bacillus tuberculosis*, of KOCH.

This word *bacillus*, new and unintelligible to many of our readers, really means, in all instances, a minute animal or vegetable parasite, which, entering the body and possessing the power of growth and reproduction therein, gives rise to the various forms of disease, according to the nature of the bacillus introduced.

The experimental research in these different cases, carefully conducted by experienced investigators, and covering a long period of time, would seem to establish as definitely as our present means of research will allow us to determine, that the presence of these parasites is really the essential cause of the disease in question.

We have had occasion, during the past few months, to note, in the columns of this journal, the occurrence of what would seem to be pneumonia from contagion.

Would it be too much of a stretch of the imagination to suppose that this disease, and, indeed, that all other diseased conditions of organic life, may be due to the presence of parasites.

It would certainly seem very plausible for us to hold this theory, in the light of modern research; and reasoning from such a basis, a broad field is opened up for the use of young, active men, who are ambitious to distinguish themselves as original investigators.

But the real, true, vital question has not yet been met, and it is in this direction that future investigation should be especially directed.

PASTEUR has succeeded in discovering a method of artificial cultivation of his bacilli, by which he can so reduce their virulence that they will be deprived of their extremely dangerous power to cause fatal disease, yet will retain sufficient of their original force to so impress the systems of the lower animals as to confer upon them immunity from the disease in its more serious and fatal form; in reality, he vaccinates them as a preventive of anthrax or splenic fever, just as the human being is vaccinated as a preventive against smallpox.

KOCH has succeeded in developing his bacilli outside of the body, artificially, for a period of six months, and then has produced tuberculosis in the bodies of animals inoculated with these artificially developed parasites.

But the practical point that we now desire, and toward which these discoveries direct our attention, is some remedy capable of destroying the vitality, and therefore the power for mischief, of these little foreign rascals. If one set of investigators will devote their time to elucidating the nature of the bacilli or parasite of any particular disease, and then themselves or others following in their footsteps will investigate and experiment until some means has been devised by which the foreign body in each particular case may be destroyed, then will we have accomplished a great practical feat in therapeutics. It is very well to discover a process by which immunity from any disease may be conferred, but until the public more fully realize the value of prophylaxis (which, thank God, they are commencing to do) it is equally or even more important to know how to stay the ravages of disease when it has become once established, and in the case of these parasitic diseases, it would seem that the most rational way to accomplish this indication would be to have and possess some measures potent to destroy the cause.

Let us trust that investigators will direct their energies in this direction, and that ere long we will have some good therapeutical results from this "*age* of bacilli." We have now a good pathological foundation upon which to erect our superstructure of therapeutics in these diseases due to bacilli; let us avail ourselves of the opportunity, and the nineteenth century will truly be *the* age of medical progress.

Notes and Comments.

Ovariotomy in a Young Girl.

In the *Medical Bulletin* Dr. W. A. Fergusson reports the following unusual case: The girl was a native of England, aged 15 years. After having complained, during her twelfth year, of acute pain in the left iliac region, it was noticed the abdomen was enlarging. This gradually increased, pushing the viscera out of position and causing her to present a truly pitiable appearance. She refused to have the tumor removed, and in order to relieve her sufferings, was tapped four times. The cyst rapidly refilled after each tapping. She became very weak and emaciated, and consented to have the tumor removed. The cyst was extensively adherent to the liver, stomach, walls of abdomen, and to a less extent to the intestines, which prolonged the operation. The tumor with its contents weighed fifty-nine and two-fifths pounds. The girl made a rapid and complete recovery.

Digestion of Cellulose.

The *Lancet* says that M. Duclaux, continuing his investigations into the digestive process, has satisfied himself that the diastase of the stomach and pancreas is without any influence on cellulose, and it may, therefore, reasonably be asked whether cellulose deserves to be ranked among alimentary substances. Experiments on the herbivora present many difficulties, but are more practicable with the gramnivorous birds; and by feeding pigeons with Saracen wheat, malt, and pearl barley he has satisfied himself that the excrements do not contain the whole of the cellulose ingested, the amount absorbed being about one-fifth of the whole. But what is the agent of this digestion? In examining the entire grains found in the crop of birds or the paunch of the ruminants, some are found with the contents entirely liquefied. The microscope shows that in these the amylaceous masses are intact, preserving the form of the cellules which they fill, but free from their envelope, and swimming in a liquid which contains thousands of minute rods, analogous to those which have been described by Van Tieghem, as the ferments of cellulose—"amylobacteria." These minute rods, by their growth, may be the means of effecting the digestion of cellulose, transforming it into dextrine and into glucose. These are found in the liquids of the gizzard, the mucous membrane of which, although a powerful absorbent, secretes no substance capable of acting on starch. It is easy to understand the important part played by this process of liquefaction of the interior of the grain on the rumination of the herbivora, and on the action of the gizzard in birds. It is certain that, once present, this influence goes on, not in the stomach, in which the acid liquid hinders their effect, but in the whole length of the intestine of the herbivora. These organisms are thus, probably, the only agents in the physiological digestion of cellulose. Truly, our range of vision regarding the action of bacteria is becoming widely extended. They appear not only to constitute the processes of disease, but even to subserve some of the functions of health.

Correspondence.

Can Two Special Systemic, or Local Activities Co-Exist?

Ed. Med. and Surg. Reporter:—

On the 23d of December, 1881, I vaccinated a boy 13 years of age. The operation was a secondary one, but it proved fairly successful. Three days after the performance of the operation a brother of the boy was found to be suffering from diphtheria, from which disease he unfortunately died six days later. Two other brothers and the father of the children subsequently became affected. The vaccinated boy and the mother of the family were the only ones that escaped, except a little girl who was early taken away from home. The mother was between four and five months gone in pregnancy. Neither of these had the disease previously.

Now, would there not seem to be some reason for believing that the vaccination in the boy's case and the pregnancy in the mother's prevented them respectively from being attacked with diphtheria?

It has long been more or less believed by many that one special activity in the system, or a part thereof, serves to prevent the occurrence of another, or others. The celebrated Dr. John Hunter was, perhaps, the first to speak explicitly and authoritatively on this interesting and important subject. In his "Treatise on the Blood, Inflammation and Gunshot Wounds," published in 1793, he says: "It appears to me, beyond a doubt, that no two actions can take place in the same constitution, nor in the same part, at one and the same time; the operations of the body are similar in this respect to actions or motions in common matter. It naturally results from that, that no two different fevers can exist in the same constitution, nor two local diseases in the same part, at the same time." These views have been combated, but I believe their correctness has not at all been entirely disproved.

In his work on the practice of medicine, Dr. Aitken ventures to affirm that "the doctrine of the incompatibility of two or more contagious diseases occurring in the same subject has been clearly proved to be erroneous. Dr. Murchison, in an admirable paper on this subject, in *The British and Foreign Medico-Chirurgical Review* for July, 1859, has clearly shown the co-existence

of variola and scarlatina; also of variola and rubeola."

Dr. G. B. Wood disposes of the matter in his work on the practice of medicine as follows: "There seems to be a certain incompatibility between the several contagious febrile complaints; so that if an individual has been exposed to the causes of two of them he will not usually be affected simultaneously with both, but one will run its course, and when it begins to decline the other will appear. or the feebler one, if it have precedence, will be superseded for a time by the more powerful, and will return and finish its course after the latter has subsided. Such is the case with measles and smallpox. Occasionally, however, we see two of these complaints apparently existing together and modifying each other, as in the cases of measles and scarlet fever."

In his "Medical Notes and Reflections," Sir Henry Holland, one of the most philosophic of modern physicians, gives the following opinion on the subject: "Though we have many instances of such seeming incongruity of two diseases, that one present in the system precludes the ingress of the other, still, there is no foundation for a general law to this effect. On the contrary, we have various proof that morbid actions derived from sources wholly different may coexist in the body, severally modifying each other, though under conditions scarcely surmised in our present knowledge.

That the effects of medicines on the system, or parts of it, will take the place of diseases, is the cardinal principle of homœopathy. Sulphur kept about the person (at the suggestion of the late Dr. Hering), in such a way as that some of it will be absorbed, has been extensively practiced, to prevent cholera. Belladonna is used by many homœopaths and others to prevent scarlet fever, and tobacco has long been used by not a few to prevent various acute general diseases. The use of counter-irritants is based on essentially the same principle.

The literature of this subject is meagre. It deserves more attention than it has yet received. More facts bearing on it are wanted. And here I may remark that the point of chief interest and value is not whether one special activity invariably prevents another, but whether it does so generally, or even in a fair proportion of cases.

THOS. S. SOZINSKEY, M.D.

Philadelphia, May 15, 1882.

Heredity.

ED. MED. AND SURG. REPORTER:—

During the discussion of Robert Koch's paper on the "Etiology of Tuberculosis," before the Congress of Medicine, in Wiesbaden, April 22d, which elicited the approval of all pathologists present, the question of heredity was brought forward, and answered by Koch in the following manner:—

It is a known fact, that the quality of the substratum has the greatest influence upon the proliferation of micro-organisms. The human body also does not always offer a uniformly good substratum to pathogenous micro organisms. Thus one individual is more easily attacked by them than another, on account of a difference in disposition toward infection. This disposition is hereditary; and hereditary tuberculosis is not a transmission of the bacilli of this disease, but the transmission of conditions which are favorable to their growth.

[Bazinsky, during the discussion, pointed out the readiness with which general tuberculosis is developed during childhood, in preference to phthisis, depending upon the great blood pressure in the lungs in comparison with that of the general circulation. Cause: conditions of muscular wall of right heart.]

Boston, Mass. F. W. VOGEL, M.D.

Feeding Invalids.

ED. MED. AND SURG. REPORTER:—

Believing, as I do, that we are too often guilty of prescribing and forcing upon our patients a certain kind of *diet*, though repulsive, regardless of the natural demand made known by the incessant and persistent craving of the system for certain articles which are forbidden them, you will confer a favor by inserting in your valuable journal the following inquiry, the result of which will be embraced in the consideration of the subject and made known in due time, viz.,

What is your experience in allowing your patients to eat whatever they crave or desire during their sickness?

1st. Do you generally direct what they should eat?

2d. Relate such cases in which your directions were not obeyed.

3d. Was the effect injurious?

4th. Was the effect beneficial?

5th. Was there any noticeable effect?

6th. State nature of disease and kind of diet taken.

The physicians throughout the country will confer a favor by sending us any information upon the subject, and to those so doing we will furnish a copy of the results of such investigation. All communications strictly confidential when so desired, and should be sent to

Delphos, O. W. H. NUDING, M.D.

NEWS AND MISCELLANY.

Kansas State Medical Association.

The Kansas State Medical Association, in session at Emporia, Kansas, May 9th and 10th, elected the following officers for the ensuing year: Dr. G. W. Haldeman, of Paola, President; Dr. Menderhall, of Newton, Vice-President; Dr. T. D. Morse, of Lawrence, Secretary; Dr. W. W. Cochran, of Atchison, Treasurer. The next meeting will be held at Topeka, commencing on the third Tuesday in May, 1883.

Darwin Memorial Fund.

A Committee has been formed in London, consisting of the leaders in zoölogy and kindred sciences, for the purpose of promoting the establishment of a Darwin Memorial Fund, to be devoted to the furtherance of biological research.

Closure of Schools Affected with Infectious Diseases.

At a recent meeting of the London Society of Medical Officers of Health, the following resolution was adopted:—

"*Resolved*, That this meeting, feeling that some dangerous infectious diseases are disseminated through the agency of public elementary schools, approves of the action of the Educational Department in investing sanitary authorities with the power of requiring the closure of such institutions, with the view to preventing the spread of such diseases."

Cinchona Cultivation in Ceylon.

The rumor that cinchona planting in Ceylon was likely to die out, on account of the unsuitableness of the climate, has been denied. The variety *officinalis*, which formed the bulk of the first planting, is the only variety unsuited to the climate. *Succirubra* and *ledgeriana* are flourishing well, the former plants, about four years old, selling freely, in any quantity offered, at $2.50 each.

Massachusetts State Medical Society.

At the recent meeting of the Massachusetts State Medical Society, it was decided, after much discussion, not to admit women to membership. The following officers were elected for the ensuing year: President, Dr. Alfred Hosmer, of Watertown; Vice President, Dr. John H. McKey, of New Bedford; Treasurer, Dr. Frank W. Draper, of Boston; Corresponding Secretary, Dr. Charles W. Swan, of Boston; Recording Secretary, Francis W. Goss, of Roxbury; Librarian, P. H. Hayden, of Boston.

Philanthropic Inconsistency.

Under the head of cruelty to animals, an exchange prints the recent bequests in a Philadelphia will, leaving $1000 to the Society for the Prevention of Cruelty to Animals, and $15,000 to the Managers of a Women's Hospital, on condition that they forever keep out all unfortunate girls from the obstetrical wards.

Items.

—Mr. Ray Lankester has been re-appointed Professor of Zoölogy and Comparative Anatomy at University College, London.

—Dr. Courbin, of Bordeaux, has detected small worms in the alveoli of a dog's lung, by microscopical examination. Some were free, some were encysted. The post-mortem established pneumonia as the cause of death.

—A very simple dropper may be made by bending a piece of glass tube at a right angle, and drawing one end out to a point. On inserting the other end into the bottle, and gently inclining the latter, some of the liquid will ascend along the tube, even before the liquid in the bottle has reached the mouth, and may be dropped at will.

OBITUARY NOTICES.

—Dr. John W. Corson, of East Orange, died on Friday, June 9th, 1882, in the 66th year of his age. Dr. Corson was a practicing physician in Brooklyn for many years, removing from there to Toronto, Canada, on account of ill health. After a few years' residence in Canada, having regained his health, he removed to East Orange, where he has resided for the past fifteen years. He was a frequent contributor to the leading medical journals, and was the author of several books published by the Harpers, of New York.

—Dr. J. J. Jennings died at his residence, No. 16 East Front street, Trenton, N. J., June 1st, 1882, from blood poisoning, the result of vaccination. It appears that Dr. Jennings vaccinated himself with bovine matter, using his pocket knife as a lancet, and soon afterwards his arm became very much swollen, and death finally resulted, as above stated. Dr. R. R. Rogers was called, and found that the inflammatory stage had passed, and that mortification had set in. The deceased had had a heavy chill and was in a high fever. The bovine matter used was the same as had been successfully used in many other cases, which leads the physicians to believe that either the system of the deceased was in an unhealthy condition at the time of the vaccination, or else there was some impure substance upon the knife blade which was used for a lancet. A well known physician remarks that probably ten thousand persons have been vaccinated during the past two months in Trenton, and that Dr. Jennings was the only fatal case resulting therefrom, while there were many deaths the result of neglecting to be vaccinated.

MARRIAGES.

BULL—KINGSBURY.—On Saturday morning, June 10th, at St. John's Church, Waterbury, Ct., by the Bishop of the diocese, assisted by the Rev. F. T. Russell and the Rev. R. R. Converse, rector of the Church, Dr. Charles Stedman Bull, of New York, and Mary, daughter of Frederick J. Kingsbury.

CHASE—GRAVES.—In Woodstock, Vt., May 16th, by Rev. S. A. Parker, Dr. M. R. Chase, of Ludlow, and Eva H. Graves, of Weston.

HIER—SMITH.—On Tuesday evening, June 6th, 1882, at the residence of the bride's mother, 639 N. Twelfth street, Philadelphia, by Rev. Jacob Todd, D.D., Dr. W. G. Hier, of Cincinnati, and Olley, daughter of Mrs. Ellen and the late Dr. Charles P. Smith.

HOAG—WARNER.—In New York city, on June 1st, 1882, by Dr. Howard Crosby, Pierre C. Hoag, M.D., and Laura, daughter of J. W. Warner, M.D.

JORDAN—GODARD.—At Beaver, Pa., March 29th, 1882, by Rev. G. W. Shaiffer, David C. Jordan, M.D., and Miss Laura E. Godard, both of New Brighton, Pa.

JULIEN—NEVINS.—At Roselle, N. J., on Thursday, June 1st, by the Rev. Matthew Julien, Dr. Alexis A. Julien and Annie Walker, daughter of Peter I. Nevins.

DEATHS.

GRAY.—In New York city, on Monday, June 5th, Dr. John F. Gray, in the 78th year of his age.

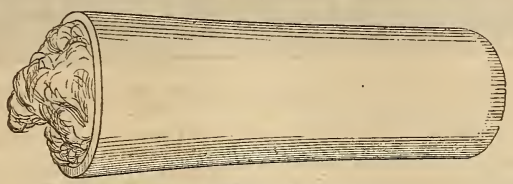
JENNINGS.—In Trenton, N. J., on the 1st of June, James L. Jennings, M.D., in the 67th year of his age.

SOLUBLE MEDICATED

HOLLOW VAGINAL SUPPOSITORIES,

For the Treatment of LEUCORRHŒA, VAGINITIS, VAGINISMUS, etc.,

(See MEDICAL AND SURGICAL REPORTER, Jan. 7, 1882, p. 7.)



CLEAN. LIGHT. RELIABLE. EFFICIENT.

These Suppositories are made of medicated gelatin, moulded in a hollow form. The interior is to be filled with either absorbent, carbolized, or salicylized cotton, so as to act as a support, and keep the Suppository, while melting, in close contact with the vaginal walls. The following advantages are claimed for them:—

FIRST.—Being hollow, the use of a large quantity of inert material is avoided, and there is no soiling of the clothes or person.

SECOND.—The composition of which the suppository is made greatly assists the absorption of the remedy, instead of forming a greasy, slowly permeable medium, like that of a cacao butter suppository.

THIRD.—By the large amount of surface over which the medicating ingredient is distributed, absorption is greatly assisted, and the effect of the remedy very soon obtained.

FOURTH.—By their close contact and prolonged action on the mucous substance of the vagina, a much more powerful and lasting effect is obtained, than by any other similar method of local medication.

FIFTH.—Being light, the suppository remains in the upper part of the vagina, where it is most needed, and does not sink and slip out, as does the old-fashioned article made of cacao butter.

These Suppositories are neatly put up in boxes, *each box containing six of a kind only*, and are medicated as follows:—

1. Sulphate Zinc, – – 5 grs.
2. " " – – 10 "
3. Acetate " – – 10 "
4. Chloride " – – 2 "
5. Hydrastis Ext. Fld., – 10 "
6. Ext. Opium Aq., – – 1 gr.
7. " " " – – 2 grs.
8. Sulphate Morphia, – ½ gr.
9. " " – – 1 "
10. Ext. Belladonna Alc., – ½ "
11. " " " – 1 "
12. Ext. Krameria Fld, – 10 grs.
13. Catechu, Powd, – – 10 "
14. Ext. Krameria Fld., – 10 grs.
    Sulphate Morphia, – ¼ gr.
15. Ext. Hyoscyamus, – – 3 grs.
16. Ext. Hyoscyamus, – – 2 grs.
    Ext. Belladonna, – – ½ gr.
17. Ext. Aconite Rad, Fld, – 2 grs.
18. Carbolic Acid, – – 2 "
19. " " – – 4 "
19½. Iodoform, – – – 5 "
20. " – – – 10 "
21. Sulphate Zinc, – – 10 grs.
    Ext. Opium Aq, – – 2 "
22. Sulphate Zinc, – – 10 "
    Ext. Belladonna Alc., – 1 gr.
23. Sulphate Zinc, – – 10 grs.
    Sulphate Morphia, – – ½ gr.
24. Sulphate Zinc, – – 10 grs.
    Carbolic Acid, – – 1 gr.
25. Sulphate Zinc, – – 10 grs.
    Acet. Lead, – – – 8 "
    Tinct. Catechu, – – 5 "
    Ext. Opium Aq., – – 1 gr.
26. Sulphate Zinc. – – 10 grs.
    Hydrastis F. E., – – 10 "
    Carbolic Acid, – – 1 gr.
    Ext. Belladonna, – – ½ "
27. Formula of Dr. W. Thornton Parker, Plymouth, Mass.
    Sulph-carbolate Zinc, – 10 grs
    Sulphate Morphia, – – ½ gr.
28. Iodoform, – – – 5 grs.
    Ext. Belladonna, – – ½ gr.

SCOTT'S EMULSION

PURE COD LIVER OIL

WITH

HYPOPHOSPHITES OF LIME AND SODA

PERFECT, PERMANENT, PALATABLE.

The well-known virtues of this preparation, that has now been before the profession for a number of years, hardly requires comment from us. But we desire, for the information of those whose attention may not have been directed to it, to present the following facts:—

FIRST.—We use in the manufacture of our Emulsion, Cod-Liver Oil that is prepared expressly for us, and is strictly pure, which is the most important consideration to the Physician.

SECOND.—By our process of Emulsifying, we so thoroughly incorporate the Oil with the Hypophosphite Salts, that the mixture is perfectly homogeneous and remains in that condition, without the slightest separation or change, for years, unless exposed to the air or intense heat.

THIRD.—It is so palatable and easy of digestion that it can be administered to children and persons with most sensitive stomachs without the slightest repugnance, and we are confident, from the results that have been obtained in the use of this preparation, and the flattering testimonials we have received from prominent physicians, that the proper manner of administering Cod-Liver Oil, even to patients that can tolerate the crude oil, is in the form of a palatable and easily digested Emulsion. There are some in the profession who adhere to the use of the plain oil, but, with all due deference, if they will make a trial of our Emulsion, we believe their prejudices will be removed, and they will find it much more beneficial to their patients.

With all the numerous Foods, Cereals and so-called Constructive Agents of uncertain value that are being introduced the physician must sometimes be at a loss to know what to prescribe. But we are assured that the profession will bear us out in the statement that in all pulmonary troubles, especially where the lung tissue is involved, in Scrofulous children and in Anæmic women of consumptive tendencies, as well as in general nervous debility, our combination will produce results, if properly administered, unequaled by any other preparation, and most satisfactory to the physician and patient. We most respectfully ask those who have never prescribed or seen its results to give it a trial, and if you desire to make a personal inspection of it we will be pleased to send a sample by express, prepaid.

FORMULA.—50 per cent. of pure Cod-Liver Oil, 6 grains of the Hypophosphite of Lime, and 3 grains of the Hypophosphite of Soda to a fluid ounce. Emulsified with mucilage and glycerine.

BUCKTHORN CORDIAL

RHAMNUS FRANGULA.

We desire to call the attention of the profession to this preparation, and although they may be familiar with its name and general characteristics, yet, on account of there not being a preparation in the market of uniform strength and quality, may not have a proper appreciation of its value. As far as our experience goes in the various tests made by our medical friends, we can present the German bark, *Rhamnus Frangula* in the form of our *Buckthorn Cordial*, with perfect confidence that we will secure the encouragement and assistance of the profession in promoting its growth and giving it the position it deserves as a medicine. It seems to be almost a specific for Habitual Constipation and Indigestion, acting mildly but efficiently, without causing the nausea that usually accompanies the use of a cathartic. At the same time producing a tonic effect upon the bowels, so that as the patient recovers, the dose may be gradually decreased until a normal condition takes place. We use great care in the selection of the Bark, as we find it necessary that it should be of the proper age and condition, and carefully exhausted, to secure its true active principle.

We combine it with aromatics in such a manner as to make a pleasant cordial, acceptable to the most sensitive stomach. We shall be very glad to furnish samples free to all physicians, upon application, giving instructions for its use, etc. Prepared by SCOTT & BOWNE

SCOTT & BOWNE'S PALATABLE CASTOR OIL

IN AN EMULSION.

We respectfully submit the above elegant preparation to the notice of the profession, and desire them to favor us with a trial. So far as it has been tested, it has met with their entire approval; and we believe it is not only destined to take the place of the crude oil, but to be used much more extensively. In our process of emulsifying, it is not only *permanent* and *palatable*, but is deprived entirely of its griping properties. The insesti mable nature of Castor Oil as a laxative and cathartic, in the varied intestinal derangements of children, and in Diarrhœa, Colds, etc., is accepted by all, and in the available form in which we present it in a perfectly palatable mixture, deprived entirely of its nauseous, sickening properties, and kindly received by the most sensitive stomach, it must occupy the exalted position it deserves as a medicine. In its administration, it requires very little more than the crude oil, but the experience of the physician will soon guide him in its use. It is put up in 4 oz. bottles, that sell for 25 cents; also in quarts for physicians to prescribe as desired. Samples will be furnished free on application. FORMULA:—50 *per cent. of Pure Cold Pressed Castor Oil*, 15 *per cent. of Chemically Pure Glycerine.* Prepared by

NOTES ON THE USE OF PEPSINE IN MEDICINE,

WITH RECOMMENDATIONS REGARDING SACCHARATED AND PURE PEPSINE.

That many of the diseases from which mankind suffer during infant and adult life are caused by malnutrition, there can be no doubt; and the extent to which non-assimilation of the life-giving properties of food interferes with recovery from severe illness, baffling the best directed efforts of the physician, points the necessity for an agent sufficiently potent to replace the deficient principle and aid nature in renewing the degenerated tissues.

Realizing this need, the science of chemistry produced pepsine; and even if medical literature were silent as to testimony of the results obtained, the large amount manufactured and consumed would amply attest its usefulness. But such is not the case, for, after long and careful investigation on the part of practical therapeutists, it is accepted as the remedy *par excellence* in all cases where the gastric juice fails to afford a sufficient amount of ferment for the reduction of aliment to a condition suitable for healthy assimilation.

As the undoubted value of pepsine as a remedial agent became evident, competition in its manufacture was stimulated; and as a natural result, the supply was varied both in purity and strength, and the medical profession, while anxious to avail themselves of its usefulness, were nearly as often misled into erroneous conclusions regarding its efficacy, as satisfied with its results, solely in consequence of their misfortune in not using such qualities as were likely to produce the much-lauded effects. Under these circumstances, a definite understanding regarding reliable preparations is desirable, and of great importance. Pure pepsine, without acid, thoroughly triturated with finely powdered sugar of milk (saccharated pepsine*), will, without doubt, produce the perfect results in all cases where the remedy is exhibited.

Routh, in his "Infant Feeding," gives an account of a result obtained in the case of an infant. "Small, wrinkled, emaciated, four days old, yet presenting almost the appearance of decrepitude. The voice was weak but distinct, and respiration not obstructed. The mother was an excellent nurse, but, although the infant took the breast readily, it constantly threw up every meal. What passed through the bowels was unchanged, although slightly tinged with bile. Diarrhœa was also present." The usual external remedies were applied, but without avail. "Emaciation was on the increase; the child was, in fact, dying." At this stage saccharated pepsine was administered, fifteen grains divided into ten powders, mixed with a little of the mother's milk, and after the second day the diarrhœa ceased and the child appeared much stronger. Twenty days of this treatment and the child was quite well. The eminent author adds: "This is a case which speaks strongly to the convictions. If at so early a period of life, when vitality and digestion were so weak, the artificial pepsine effected a cure, *a fortiori* will it be likely to do so in the case of older children; and so I have found it in practice. The digestive powers are thus assisted, and the food, which before was useless because undigested, readily becomes assimilated."

When administering pepsine, the slight acidity of the natural fluid should be produced as nearly as possible, and, as the necessities differ with the circumstances, it is desirable that the preparation be quite free from acidulation, and the proper dose be given in combination with the requisite amount of dilute acid. Of Kidder & Laird's pure pepsine, five to ten grains for an adult can, if necessary, be taken in an ounce of water, with five drops of muriatic acid.

For infants, however, the saccharated pepsine will be found to yield the most satisfactory results, and the acid should be dispensed with. Quantitatively it represents one-tenth of the strength of pure pepsine; but it has been found to be but about one-fourth less in efficacy. The absence of acid, which would otherwise tend to produce harmful results, will be recognized when it is considered that even the slight acidity of most cow's milk, when used as food for infants, is sufficient to disagree with them.

With regard to the proper time for its administration, as before or after taking of food, opinions vary, but reason would suggest that about half an hour before eating will afford the ferment a sufficient time to combine with the existing condition of the stomach, and produce the most natural effect upon the food when it has been acted upon by the salivary fluids in its passage to the stomach.

When once the formation of peptone has been established in the stomach, and as strength is acquired the system will soon respond toward resuming the natural production of its normal fluids. Thus it is that many of the disorders of digestion which accompany severe attacks of fever, phthisis, etc., and also the exceedingly sensitive condition of the stomach caused by vomiting in pregnancy and alcoholism, are controlled, and a natural condition resumed.

Having mentioned the necessity of great care in the selection of pepsine, with reference to its purity and strength, it is proper to say that, even with the superior article above recommended, negative results may be obtained, unless attention is given to the form of its administration. Combinations beyond those above mentioned are not advised, but rather discouraged, as many of the substances usually recommended as efficacious with it are incompatible and render the pepsine inert.

* Saccharated pepsine, free from acid, is prepared by Messrs. Kidder & Laird, No 83 John Street, New York, who generously furnish samples of both this and the pure pepsine, free of charge, upon application.

1264-1315

IN MORNING SICKNESS

AND OTHER DISEASES

INCIDENT TO PREGNANCY.

The action of the Acid Phosphate upon the system during pregnancy is very effective; the morning sickness being treated with good results; and where indigestion is a sympathetic trouble it has been found a valuable and pleasant remedy.

In cases of exhaustion and nervous prostration from lactation, it has been used with excellent results.

During pregnancy the consumption of phosphate of lime is very great; so that at this period of woman's life fractures heal, if at all, with great difficulty. The Acid Phosphate supplies the phosphates needed at such times.

DR. D. T. NELSON, of Chicago, says: "I find Horsford's Acid Phosphate a pleasant and valuable remedy in indigestion, particularly in pregnant women."

DR. W. L. ATLEE, of Philadelphia, says: "Having used Horsford's Acid Phosphate very extensively in my practice, which consists mostly of uterine diseases and disorders incident thereto, it is with pleasure I attest my appreciation of its usefulness."

Let the patient put eight or ten drops of Acid Phosphate into half a glass of cold water, and take a sip of it, say a few minutes before rising, or whenever the sickness or nausea is coming on.

It is equally effective in hot water, or tea without milk or sugar, and to some may thus be more palatable. In such cases use the same dilution as above. Some constitutions may need a stronger dilution, which fact experience alone can decide.

Prices reasonable. Pamphlet giving further particulars mailed free on application to manufacturers.

Physicians desiring to test it will be furnished a bottle free of expense, except express charges.

MANUFACTURED BY THE

RUMFORD CHEMICAL WORKS

1297-1348 PROVIDENCE, R. I.

An experience of more than a quarter of a century convinces us that sugar, properly applied, is the only correct coating for a pill.

Physicians should be careful to specify Warner & Co., when prescribing or ordering.

Special attention is called to the following selected Recipes prepared for Physicians' Prescriptions.

PIL: PHOSPHORI COMP: (WARNER & CO.) ℞. Phosphori, - - 1-100 gr. Ext. Nuc. Vom. - ¼ gr.

THERAPEUTICS.—As a nerve tonic and stimulant, this form of pill is well adapted for such nervous disorders as are associated with impaired nutrition and spinal debility, increasing the appetite and stimulating digestion.

The practical value of Phosphorus as a therapeutic agent, and its applicability to the cure of disease, and especially in those varied disordered conditions consequent upon OVERWORK, which are characteristic of modern civilization.

Pil. Phosphori Comp. may be taken, one or two pills three times daily, after eating.

Price, per 100, $1.50.

PIL: IODOFORM ET FERRI. (WARNER & CO.) ℞. Iodoform, - - 1 gr. Ferri Redacti, - 1¼ gr.

THERAPEUTICS.—A powerful general tonic and alterative, valuable as a remedy in Anæmia, Scrofula, Neuralgia, Chlorosis, Rheumatism, etc.

Pil. Iodoform et Ferri may be given in doses of from one to two pills, as occasion may require.

Price, per 100, $2.00.

PIL: DIGESTIVA. (WARNER & CO.) ℞. Pepsin Conc't, 1 gr. Gingerine, 1-16 gr. Pv. Nuc. Vom., ¼ gr. Sulphur, ⅛ gr.

THERAPEUTICS.—Useful in relieving various forms of Dyspepsia and Indigestion, and of permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. It is also a gentle laxative and excellent dinner pill, may be taken one after dinner, or one before each meal, three times daily.

Price, per 100, 75 cts.

PIL: CALCIUM SULPHIDE. (WARNER & CO.) 1-10, ¼, ½ & 1 gr. each.

THERAPEUTICS.—Extremely useful in the treatment of acne, scrofula and cutaneous diseases.

Sulphide of Calcium is usually administered in doses of from 1-10 to ¼ grain four times daily, gradually increasing the dose to one grain six times daily, or according to the progress or severity of the case.

Price, per 100, 1-10 gr. .50; 1-4 gr. .60; 1-2 gr. .75; 1 gr. $1.00.

WARNER & CO.'S PILLS MAY BE OBTAINED FROM ALL DRUGGISTS, OR BY MAIL, ON RECEIPT OF PRICE.

It is most efficacious when taken in the morning fasting, warmed to a temperature not below 60°, or when an equal quantity of hot water is added to it. 1273-1325eow

CRINON'S HÆMOGLOBIN.

The Albuminoid Ferruginous Principle of Blood.

HÆMOGLOBIN is the only physiological chalybeate of the blood, it forms the most powerful of tonics, and at the same time a most nourishing food. It is especially useful in cases of *Anæmia, Chlorosis, Cachexias, Exhaustion* caused by excess of work, nervous debility, fatigue resulting from parturition and lactation. It replaces entirely liquid blood, which has been recommended and used with success in *Phthisis* and *wasting away.*

It is offered in two forms: In cachets (waters), 60 of which are contained in a box; combined with chocolate in small squares, 30 of which are in a box; both forms can be sent by mail.

Prepared by C. CRINON, Paris, Pharmacist of the first class, Laureate of the Hospitals of Paris. Samples may be obtained by application to

E. FOUGERA & CO., New York, Agents for the U. S.

DOCTOR RABUTEAU'S

(Laureate of the Institute of France.)

DRAGEES, ELIXIR & SYRUP

OF IRON.

"The experiments made in the hospitals of Paris have demonstrated that *Dr. Rabuteau's Dragees, Elixir and Syrup* regenerate the red globules of the blood with a rapidity never observed with the use of the other ferruginous preparations. These results have been proved by the various *Compt-Globules.*

"The ferruginous preparations of *Dr. Rabuteau* do not cause any constipation, and are perfectly tolerated by the weakest persons."—*Gazette des Hospitaux.*

Dr. Rabuteau's Elixir is prescribed when some difficulty is experienced in swallowing the Dragees; it is especially adapted to weak persons, whose digestive functions need strengthening or stimulating.

Dr. Rabuteau's Syrup is especially prepared for children, who take it readily, because of its agreeable taste.

FOUGERA'S COMPOUND IODINISED

COD LIVER OIL.

Since the introduction of this oil in 1858, it has been found to be superior to all other kinds of Cod Liver Oil for the treatment of **General Debility, Consumption, Scrofula, Rickets, etc.**

It possesses not only all the **nourishing** qualities of the best Cod Liver Oil, but also the **tonic, stimulant** and **alterative** properties of **Iodine, Bromine** and **Phosphorus,** which are added in such proportions as to render it therapeutically five times as efficacious as pure Cod Liver Oil.

Through its **increased curative action, FOUGERA'S COD LIVER OIL** will be found to cure disease in a much shorter time than the pure oil; while favorable results will be obtained by its use in many advanced cases when the pure Cod Liver Oil would fail entirely.

FOUGERA'S READY-MADE MUSTARD PLASTERS.

A most useful, convenient, clean, and economical preparation. Not liable to change if kept in a dry place. Made of two strengths. Plasters No. 1, of pure mustard; Plasters No. 2, of one-half mustard. Price 40 cents, the tin box, or tin roll, of 10 plasters each. DIRECTIONS.—Dip the Plaster, or Plasters, a minute or two, in cold water; apply on the part, and cover with a band.

FOUGERA'S COMPOUND ICELAND MOSS PASTE.

(Iceland Moss, Lactucarium, Ipecac and Tolu.)

Used with great success against nervous and convulsive coughs, Whooping Cough, Acute Bronchitis, Chronic Catarrh, Influenza, etc.

Wakefulness, Cough, and other sufferings in Consumption, are greatly relieved by the soothing and expectorant properties of this Paste.

FOUGERA'S IODO-FERRO-PHOSPHATED ELIXIR OF HORSE-RADISH.

This Elixir contains Iodine, Pyrophosphate of Iron, the active principles of antiscorbutic and aromatic plants, and acts as a **tonic, stimulant, emmenagogue,** and a **powerful regenerator of the blood.** It is an invaluable remedy for all constitutional disorders due to the impurity and poverty of the blood. One of the advantages of this new preparation consists in combining the virtues of Iodine and Iron without the inky taste of Iodide of Iron.

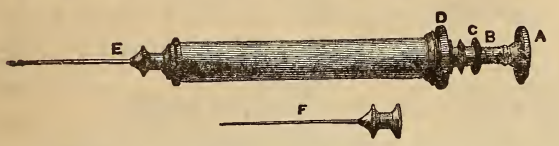
NEW HYPODERMIC SYRINGES.



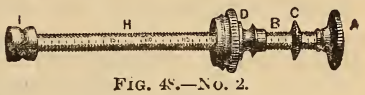


FIG. 48.—No. 2.

These cuts (two-thirds the actual size) represent a New Hypodermic Syringe of our Manufacture. With the exception of the needles, it is of German Silver, a material chosen as possessing, next to steel, the greatest rigidity and durability, while free from liability to oxydation. The barrel is formed by a process peculiar to ourselves, securing uniformity of calibre without soldered joint or seam. It is plated inside and outside with nickel. The piston is packed in the double parachute form, with leather prepared expressly for the purpose. It will be found to retain its elasticity, to operate smoothly, to resist all tendency of fluid to pass above, as of air below it. A nicely-engraved scale upon the piston-rod indicates minims, thirty being the capacity of the syringe.

Syringes Nos. 2, 3, and 4 have also a screw thread upon the piston-rod, and a traverse nut, thereby favoring the utmost nicety in the graduation of doses.

No. 3, Compact, has hollow piston-rod to receive one needle, also a protecting cover and fluid retainer; it may be carried in the Pocket Instrument or Vial Case, or without any case.

No. 4, Compact, is like No. 3, with the addition of a second needle, carried upon the syringe in the usual place, protected by a metal shield.

Nos. 1 and 2 are put up in neat morocco-covered case, with vial.

Two sizes of needles are furnished with each instrument, Nos. 1, 2, and 4; one only with No 3. They are of refined steel, carefully tempered, and thoroughly plated with gold; they are of small diameter and large relative calibre, sharpened to such an angle as will offer least resistance to penetration, and therefore cause least pain. At the point of union with the socket they are reinforced with an outer covering of German silver, thereby overcoming the tendency to become broken at this place. They are connected with the barrels by a screw thread.

Prices: No. 1, *$3 50* No. 2, *$4.00* Postage, .03
" No. 3, *2.50* No. 4, *3.50* " .02

No. 3.

These Syringes are so thoroughly and strongly made as to be free from the annoying accidents common to most Hypodermic Syringes; and we believe that, for convenience, durability, and nicety of construction, they have no superior.

BUFFALO LITHIA WATER.

FOR

BRIGHT'S DISEASE OF THE KIDNEYS, THE GOUTY OR URIC ACID DIATHESIS, CHRONIC INFLAMMATIONS OF THE BLADDER, ETC.

Dr. Wm. A. Hammond, of New York, Surgeon General U. S. Army (retired), Professor of Diseases of the Mind and Nervous System in the University of New York, etc.

"I have for some time made use of the Buffalo Lithia Water in cases of affections of the Nervous System, complicated with Bright's Disease of the Kidneys, or with a Gouty Diathesis. The results have been eminently satisfactory. Lithia has for many years been a favorite remedy with me in like cases, but the Buffalo Water certainly acts better than any extemporaneous solution of the Lithia Salts, and is, moreover, better borne by the stomach. I also often prescribe it in those cases of Cerebral Hyperæmia, *resulting from mental overwork*—in which the condition called Nervous Dyspepsia exists—and generally with marked benefit."

Dr. J. Marion Sims, of New York, says of this water, in general terms:—

"I have used in my practice the Buffalo Lithia Water, Spring No. 2, for two years past, and have, in many cases, found it highly efficacious."

Dr. Alexander B. Mott, of New York, Professor Surgery, Bellevue Hospital Medical College, Surgeon Bellevue Hospital.

"I have made sufficient use of the Buffalo Lithia Water to be satisfied that it possesses very valuable therapeutic properties. In the Gouty Diathesis, Chronic Inflammation of the Bladder, and other diseases affecting the Urinary Organs, it may be relied on to give the most satisfactory results."

Dr. Hunter McGuire, Richmond, Virginia, late Professor Surgery Medical College of Virginia; Medical Director on the Staff of Gen. T. J. (Stonewall) Jackson; Vice-President of the International Medical Congress; Vice-President American Medical Association.

"Buffalo Lithia Water as an Alkaline Diuretic is invaluable. In Uric Acid Gravel, and, indeed, in diseases generally of the Uric Acid Diathesis, it will be found a remedy of extraordinary potency. I have prescribed it in cases of Old Rheumatic Gout, which had resisted the ordinary remedies, with wonderfully good results. I have also used it in my own case, being a great sufferer from this malady, and have derived more benefit from it than from any other remedy. It has remarkable adaptation in diseases of the Digestive Organs. In that condition especially known as Nervous Dyspepsia, caused by over-mental taxation, where, too, there is an excess of acid in the process of digestion, the happiest results may be anticipated from it.

Dr. Robert Battey, of Georgia, Suggestor of Battey's Operation; Member of the American Medical Association, etc.

"I would state that I have been using the Buffalo Lithia Water No. 2, in my practice for three years past, in cases of Chronic Inflammation of the Bladder, whether induced by STONE, by ENLARGED PROSTATE in the aged, or by neglected GONORRHŒA, and have secured excellent results, which encourage me to prescribe it for the future."

This Water, in Cases of One Dozen Half-Gallon Bottles, $5.00 per Case, at the Springs.

On Sale in Philadelphia by JOHNSTON, HOLLOWAY & CO.; JOHN WYETH & BRO.; FRENCH, RICHARDS & CO.

Springs Pamphlet sent to any address. Springs open from 1st of June to 1st of October.

OSMUN'S
PREPARED COD LIVER OIL
—AND—
LACTO-PHOSPHATE of LIME.

Sold by Druggists.

SMITHTOWN BRANCH, L. I., December 18, 1876.

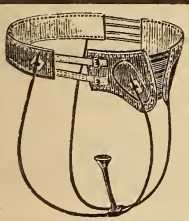
C. A. OSMUN, ESQ., 13 Seventh Avenue, New York.

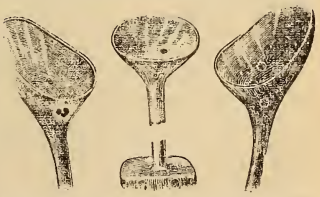
DEAR SIR:—I have been prescribing your preparation of Cod Liver Oil, combined with Lacto-phosphate of Lime, for about five years, and still recommend it with increased confidence, as I have found its great value in most cases of pulmonary affections in the earlier stages, in affections connected with a scrofulous diathesis, and in strumous diseases generally.

Very truly yours, H. B. WILLS, M.D.

1242-93 *DEPOT—13 Seventh Avenue, New York.*

DR. McINTOSH'S
NATURAL UTERINE SUPPORTER.





No instrument has ever been placed before the medical profession which has given such universal satisfaction. The combination is such that the physician is able to meet every indication of Uterine Displacements. Falling Womb, Anteversion, Retroversion and Flexions are overcome by this instrument, where others fail. This is proven by the fact that, since its introduction to the profession it has come into more general use than all other instruments combined.

Among the many reasons which recommend this Supporter to the physician is its self-adjusting qualities The physician, after applying it, need have no fear that he will be called in haste to remove or readjust it, as is often the case with rings and various pessaries held in position by pressure against the vaginal wall, as the patient can remove it at will. and replace it without assistance.

The Abdominal Supporter is a broad morocco leather belt, with elastic straps to buckle around the hips, with concave front, so shaped as to hold up the abdomen. The Uterine Support is a cup and stem, made of highly polished hard rubber, very light and durable, shaped to fit the neck of the womb, with openings for the secretions to pass out, as shown by the cuts. Cups are made with extended lips, to correct flexions and versions of the womb. The cup and stem is suspended to the belt by two soft elastic rubber tubes, which are fastened to the front of the belt by simple loops. pass down through the stem of the cup and up to the back of the belt. These soft rubber tubes being elastic, adapt themselves to all the varying positions of the body, and perform the service of the ligaments of the womb. The instrument is very comfortable to the patient, can be removed or replaced by her at will, can be worn at all times, will not interfere with nature's necessities, will not corrode, and is lighter than metal. It will answer for all cases of Anteversion, Retroversions, or any Flexions of the womb, and is used by the leading physicians with never-failing success, even in the most difficult cases.

Our Reduced Prices are to Physicians, $6.00; to Patients, $10.00.

Instruments sent by mail, at our risk, on receipt of price, or by Express, C. O. D., with the Express charges for returning the money added.

☞ CAUTION.—Owing to the great sale and popularity of our instrument various and base imitations are sold by unscrupulous parties. In order to get the genuine, it is best to order direct from us.

DR. McINTOSH'S NATURAL UTERINE SUPPORTER CO.,
192 Jackson Street, Chicago, Ill.

Our valuable pamphlet, "Some Practical Facts about Displacements of the Womb," will be sent you free on application. 1281-1332

For Consumption and Wasting Diseases.

HYDROLEINE

Has been proved of the highest value in CONSUMPTION and all WASTING DISEASES, invariably producing IMMEDIATE INCREASE in FLESH and WEIGHT.

FORMULA OF HYDROLEINE.

Each dose of two teaspoonfuls, equal to 120 drops, contains:

Pure Oil,	**80 m. (drops.)**	**Soda,**	**1-3 grain.**
Distilled Water,	**35 m.**	**Boric Acid,**	**1-4 "**
Soluble Pancreatin,	**5 grains.**	**Hyocholic Acid,**	**1-20 "**

DOSE.—Two teaspoonfuls alone, or mixed with twice the quantity of soft water, to be taken thrice daily, with meals.

The principles upon which this discovery is based have been described in a treatise on "THE DIGESTION AND ASSIMILATION OF FATS IN THE HUMAN BODY," by H. C. BARTLETT, PH.D., F.C.S., and the experiments which were made, together with cases illustrating the effect of Hydrated Oil in practice, are concisely stated in a treatise on "CONSUMPTION AND WASTING DISEASES," by G. OVEREND DREWRY, M.D.

In these treatises the Chemistry and Physiology of the Digestion of the Fats and Oils is made clear, not only by the description of a large number of experiments scientifically conducted, but by cases in which the deductions are most fully borne out by the results.

☞ *Copies of these valuable works will be sent free, on application, to all who mention THE MEDICAL AND SURGICAL REPORTER.*

HYDRATED OIL,

HYDROLEINE,

WATER AND OIL,

May be described as partially digested oil, which will nourish and produce increase in weight in those cases where oils or fats not so treated are difficult or impossible to digest. In CONSUMPTION and other WASTING DISEASES the most prominent symptom is EMACIATION, of which the first is the starvation of the fatty tissues of the body, including the brain and nerves. This tendency to emaciation and loss of weight is arrested by the regular use of HYDROLEINE, which may be discontinued when the usual average weight has been permanently regained.

The ordinary so-called emulsions of Cod-liver oil and other fats, WHETHER PANCREATIZED OR NOT, merely remain in the form of a coarse mechanical mixture for a short time after agitation. The digestion of oil having in no sense been artificially produced, still devolves upon those functional powers the deficiency of which is the most prominent symptom in these cases.

HYDROLEINE is not a patent medicine or a secret preparation; the formula is on every bottle. Can be taken by the most delicate stomach; is immediately assimilated.

The permanence and perfection of the emulsion, and the extreme solubility of the HYDRATED OIL, solely prepared and sold by us under the name of HYDROLEINE, is shown by its retaining its cream-like condition as long as the purest Cod-liver Oil will retain its sweetness. Unlike the preparations mentioned, or simple Cod-liver Oil, it produces no unpleasant eructation or sense of nausea, and should be taken in such very much smaller doses, according to the directions, as will insure its complete assimilation; this, at the same time, renders its use economical in the highest degree.

To brain-workers of all classes Hydrated Oil is invaluable, supplying as it does the true brain food.

Economical in use—certain in result Tonic—Digestive and Highly Nutritive.

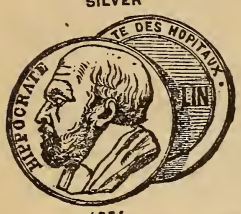
MATHEY-CAYLUS' GLUTEN

SILVER

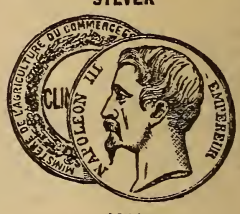


CAPSULES

OF

PURE COPAIBA AND OTHER MEDICINES.

SILVER



Adapted and recommended for the cure of recent or chronic Gleets, Fluor Albus, etc., etc.

The MATHEY-CAYLUS' CAPSULES, *coated with gluten*, present the most perfect mode for administering Copaiba, Cubebs, Norway Tar, Turpentine, and other remedies, the disagreeable odor and taste of which are often a hindrance to their use. This mode of preparing capsules, which has been approved by the Academy of Medicine, has been recommended in their clinical lectures by eminent Professors in the hospitals of Paris, as well as in those of New York and London.

By the first physicians of the hospitals of Paris, London, and New York.

SPECIAL ADVANTAGES OF MATHEY-CAYLUS' GLUTEN CAPSULES.—Being formed of thin, transparent, and readily assimilated coating, they so cover and disguise the medicine to be given, that it can be taken without disgust, but with ease. In this respect, they differ widely from the gelatine capsules, which have a hard, thick coating, which swells beyond measure, in the stomach, are hard to be swallowed, and what is of great importance, they create disturbance in the digestive functions.

The special advantage of the coating of gluten consists in the fact that, notwithstanding its extra thinness, and although it softens under the action of the gastric juice, it can pass the stomach without breaking, and only in the intestines is the medicinal matter liberated; this accounts for the fact that Mathey-Caylus' Capsules never cause the nausea, eructations, and dyspeptic symptoms, which are complained of by many persons using other preparations.

Finally, their regular ovoid form, which is so favorable to swallowing, their pleasant appearance, which dispels all disgust, and the advantage of being entirely free from taste and smell, recommend the use of these capsules even to the most delicate persons.

Thankful to the Medical Profession for the liberal patronage heretofore bestowed upon us, we hope that they will continue their favors, and we are convinced that they will never have any reason to regret the generous welcome they have given to our preparations.

MATHEY-CAYLUS' CAPSULES are never sold, except in bottles having the following inscription printed in the glass: MATHEY-CAYLUS A PARIS. And each bottle contains 64 capsules, making them the cheapest capsules in the market.

The following different kinds of Mathey-Caylus' Gluten Capsules are now offered:

COPAIBA AND TANNIC ACID,
COPAIBA AND S. N. OF BISMUTH,
COPAIBA AND CATECHU,
COPAIBA AND MAGNESIA,
COPAIBA, CUBEBS AND ALUM,
COPAIBA, CUBEBS AND RHATANY,
COPAIBA AND RHATANY,

JOHNSTONE'S IMPROVED

ADAPTABLE POROUS FELT SPLINTS.

AHL'S SPLINT MANUFACTURING COMPANY, LIMITED,

123 & 125 South Eleventh Street, PHILADELPHIA, PA.

THE ADAPTABLE POROUS SPLINTS, invented and improved by W. H. JOHNSTONE, have been tested extensively in both civil and military practice for a number of years, and have been endorsed and recommended in the most unqualified manner by the celebrated and distinguished Surgeons of America.

Their *porosity* is a peculiar and a valuable property. While the material is firm and insoluble, it permits readily the passage of air and fluids, so that, on one hand, the heat from the inflamed surface, the perspiration, and the morbid exhalations, are not confined, to the detriment of the patient, *as is the case in every other kind of splint*, but pass off freely; and on the other hand, lotions of cold or warm water, medicated or not with weak alcohol, carbolic acid, arnica, tincture, solutions of the sulphites, etc., can be constantly applied without disturbing the dressings. This, it will readily be seen, is a most invaluable property when the parts are bruised, lacerated, filled with extravasated blood, or erysipelatous, and give these splints a conspicuous advantage over all others.

From FRANK H. HAMILTON, M. D., Professor of Fractures and Dislocations in the Bellevue Hospital Medical College, author of "A Treatise on Fractures and Dislocations," etc.

Having examined carefully *JOHNSTONE'S IMPROVED ADAPTABLE POROUS FELT SPLINTS*, I feel warranted in recommending them to the Profession as superior to all other manufactured splints now in use. They possess all the essential qualities of a good splint, having firmness, pliability and lightness.

FRANK H. HAMILTON, M. D.,
Prof. Military Surgery and Fractures and Dislocations, Bellevue Hospital Col.

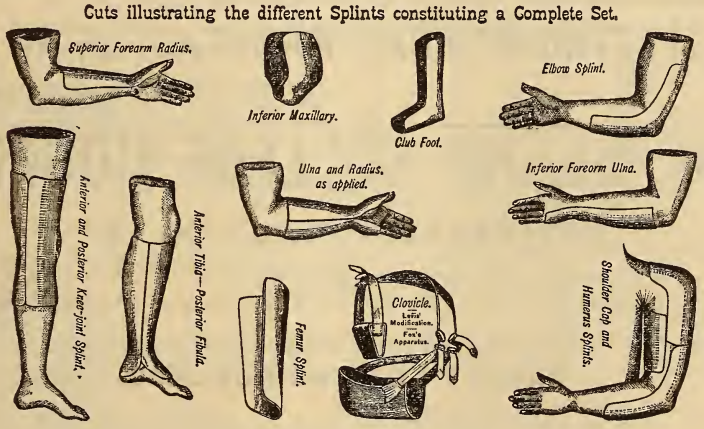
From PROF. D. HAYES AGNEW, Prof. Surgery, University of Penna.

1611 CHESTNUT STREET, PHILADELPHIA, *February 6th*, 1879.

The Adaptable Felt Splints, formerly known as those of Dr. Ahl, with the improvement now made by W. H. Johnstone, which renders them in every way superior to the former, I regard as very excellent appliances in the treatment of fractures.

D. HAYES AGNEW,
Prof. Surgery, University of Pennsylvania.

Cuts illustrating the different Splints constituting a Complete Set.



SPECIAL NOTICE TO THE PROFESSION AND TRADE.

Our *policy* heretofore in the introduction of **JOHNSTONE'S IMPROVED ADAPTABLE POROUS FELT SPLINTS**, has been to confine the sales and business negotiations directly to the Doctors themselves, declining in every case to sell our goods through Dealers; we having assured the Profession generally, both through our agents and catalogues, that *JOHNSTONE'S IMPROVED SPLINTS* could only be obtained by subscription.

We wish to announce, that owing to the large demand for our goods and the constant importunity on the part of *Surgeons* everywhere to place our Splints on sale with their Instrument Dealer or Druggist, to afford them greater convenience and facility in obtaining the pieces in duplicate, **we have at last acceded to that request, and hereafter** *JOHNSTONE'S CELEBRATED FELT SPLINTS* **can be obtained at most dealers in Instruments and Drugs throughout the United States, at the same price which they were heretofore sold, viz:**

A complete set, embracing fifty (50) pieces—twenty-five for adults and twenty-five for children—is thirty ($30) dollars. Extra or duplicate pieces can always be obtained from your DEALER, at one dollar each.

JOHNSTONE'S CELEBRATED SPINAL JACKET, for Curvatures and Deformities, have met with unparalleled success, and, from their merit, secured the unqualified endorsement and approbation of our celebrated orthopædic specialists, and particular expression of gratitude from the patients who are wearing them. For full information, send for Descriptive Circulars.

Should your Instrument dealer fail to have a supply of our Splints, and decline to carry them in stock, orders sent to us will receive prompt attention.

AHL'S SPLINT MANUFACTURING CO., Limit

LONG ISLAND COLLEGE HOSPITAL,

BROOKLYN, N. Y.

☞THE READING AND RECITATION TERM will commence September 28th, 1881, and close at the beginning of the Regular Term.

☞THE REGULAR TERM will open January 25th, 1882, and continue five months.

FACULTY OF THE COLLEGE.

DANIEL AYRES, M.D., LL.D.,
Emeritus Professor of Surgical Pathology and Clinical Surgery.

SAMUEL G. ARMOR, M.D., LL.D.,
Professor of the Principles and Practice of Medicine and Clinical Medicine, and Dean of the Faculty.

GEORGE W. PLYMPTON, M.D.,
Professor of Chemistry and Toxicology

CORYDON L. FORD, M.D.,
Professor of Anatomy.

ALEXAND J. C. SKENE, M.D.,
Professor of the Medical and Surgical Diseases of Women, and Diseases of Children.

JARVIS S. WIGHT, M.D.,
Professor of the Principles and Practice of Surgery and Clinical Surgery and Registrar.

JOSEPH H. RAYMOND, M.D.,
Professor of Physiology and Microscopic Anatomy.

EDWARD SEAMAN BUNKER, M.D.,
Professor of Histology and General Pathology.

JOHN A. McCORKLE, M.D.,
Professor of Materia Medica and Therapeutics.

CHARLES JEWETT, M.D.,
Professor of Obstetrics.

The Faculty, by the establishment of THE READING AND RECITATION TERM, give a *thorough systematic training in the elements of medical science.* To this end, the instruction for junior students is confined to the *primary branches*, and consists mainly of recitations from standard text-books. Senior students are admitted to higher studies.

The Regular Term embraces the usual Course of Didactic and Clinical Lectures, and a thorough graded system of instruction in the practical branches.

There are over 12,000 patients treated annually in the Hospital, which is under the control of the College authorities, and therefore available for practical teaching. Advanced students in classes of ten or more accompany the Clinical Teacher in his daily hospital service. By this system of constant rotation of classes from the Medical to the Surgical wards of the Hospital, the student receives the largest possible amount of instruction daily in all the practical branches. This mode of teaching is *peculiar* to the Long Island College Hospital, the Clinical advantages of which are unsurpassed in this country.

UNIVERSITY OF PENNSYLVANIA.

POST-GRADUATE INSTRUCTION.

A Post-Graduate Course has been organized for Bedside and Dispensary Instruction in the following named branches:—

ON PHYSICAL DIAGNOSIS AND CLINICAL MEDICINE, Prof. WM. PEPPER and Dr. ED. T. BRUEN.
" NERVOUS DISEASES AND ELECTRO-THERAPEUTICS, - - - Prof. H. C. WOOD.
" DERMATOLOGY, - - - - - - - - - - - Prof. L. A. DUHRING.
" OTOLOGY. - - - - - - - - - - - - Dr. GEO. STRAWBRIDGE.
" OPHTHALMOLOGY, - - - - - - - - - - - Dr. S. D. RISLEY.
" GYNÆCOLOGY, - - - - - - - - - - - - Dr. B. F. BAER.
" LARYNGOSCOPY, - - - - - - - - - - - - Dr. C. SEILER.
" OPERATIVE SURGERY AND VENEREAL DISEASES, - - - Dr. J. WM. WHITE.

Two courses will be given annually; beginning the first week in November and the first week in April; continuing three months, two lectures each week. A certificat will be given to each person having taken the full course. Fee $100, for seven branches—elective- or $25 for each branch taken separately, invariably in advance. For further information apply to the undersigned, or any of the Lecturers.

McINTOSH COMBINED

Galvanic AND Faradic Battery.

THIS CELEBRATED BATTERY COMBINES BOTH THE GALVANIC AND FARADIC CURRENT,

Which can be used separately or combined. Any strength and intensity desired can be obtained for use in Electro-therapeutics. THIS BATTERY is constructed on an IMPROVED PLAN, as follows: The zinc and carbon plates are arranged in couples, securely clamped to hard rubber plates, with thumb screws. These screws are also used for binding posts. All the connections are positive. The cells are made in sections of six, of hard rubber, with hard rubber drip cup. The following points of excellence render our Batteries superior to others:

1. They combine the only Portable Galvanic and Faradic Battery in one case.

2. They weigh one-half less than other Batteries of the same number of cells.

3. The cel's are made insections of six, of one solid piece of hard, vulcanized rubber; by this arrangement they can be emptied, cleaned and filled as easily and quickly as one cell, and will not crack, break or leak.
4. A hard rubber drip cup is placed by the side of each section of cells, to receive the zinc and carbon plates when removed from them. By this arrangement we avoid the use of absorbent materials and soiling the Battery
5. The Hydrostat is perfect. The rubber plates which hold the elements project over on one side enough to cover the cells when the zinc and carbon plates are placed in the drip cups. The under side of this projection is covered with thick, soft rubber, which is securely clamped to the cells sections, and makes them water tight.
6. This is the only Battery in which the zinc and carbon plates can be kept clean by simply rinsing them.
7. A zinc or carbon plate can be removed by simply loosening a binding post; and all parts of the Battery can be duplicated, as like parts are made exactly alike. We will be pleased to send circulars and our illustrated catalogue giving full information, price, etc., free, upon application

TO PHYSICIANS.

IODIA.

FORMULA.—Iodia is a combination of Active Principles obtained from the Green Roots of STILLINGIA, HELONIAS, SAXIFRAGA, Menispermum, and Aromatics. Each *fluid* drachm also contains *five* grains IOD.-POTAS. and *three* grains PHOS.-IRON.

DOSE.—One or two *fluid* drachms (more or less, as indicated) *three* times a day, before meals.

IODIA is the *Ideal* Alterative. It has been LARGELY PRESCRIBED in Syphilitic, Scrofulous, Cutaneous, and Female Diseases, and has an Established Reputation as being the best Alterative ever introduced to the Profession.

W. H. BYFORD, A.M., M.D., CHICAGO, ILL.

M. F. COOMES, M.D., LOUISVILLE, KY.
Prof. Physiology and Ophthalmology, Kentucky School of Medicine.

D. OVERLY CRIST, M.D., INDIANAPOLIS, IND.
Prof. Materia Medica and Therapeutics, Central College Physicians and Surgeons.

N. W. WEBBER, M.D., DETROIT, MICH.
Prof. Medical and Surgical Diseases of Women and Clinical Gynæcology, Detroit Medical College.

JOHN A. McCORKLE, M.D., BROOKLYN, N. Y.
Prof. Materia Medica and Therapeutics, Long Island College Hospital.

J. M. BIGELOW, M.D., ALBANY, N. Y.
Prof. Materia Medica and Therapeutics, Albany Medical College.

J. L. WHITE, M.D., BLOOMINGTON, ILL.
Ex-President Illinois State Medical Society.

BROMIDIA.

FORMULA.—Every *fluid drachm* contains fifteen grains EACH of pure Brom.-Potas. and *purified* Chloral, and one-eighth grain EACH of *gen. imp. ext.* Cannabis-Ind. and Hyoscyam.

DOSE.—*One-half* to *one fluid drachm* in WATER or SYRUP, every hour until sleep is produced.

BROMIDIA is *the* Hypnotic *par excellence*. It produces refreshing sleep, and is *exceedingly* valuable in Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, etc., and will relieve *when opiates fail. Unlike* preparations of opium, *it does not lock up the secretions.* In the Restlessness and Delirium of Fevers *it is absolutely invaluable.*

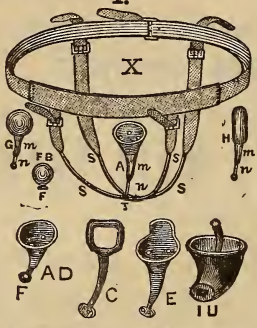
STAUFER'S
HARD RUBBER INSTRUMENTS AND PRICE LIST.

SPRING STEM SUPPORTERS.

1.



Prices.—Spring Stem Prolapsus and Procidentia Cup A, on Covered Silk Elastic and Coutil Finished Belt X, $7.00. On Z, Fig. 5, $6.00. On Y, Cotton, $7.00; Satin, $7.50; and Coutil, $8.00.

Spring Stem, Globe Top G, Oblong H, or I U, the same on either belt as A.

Retroversion E, on X, or Y, Cotton, $8.00. On Z, Fig. 5, $7.00. On Y, Satin, $8.50; Coutil, $9.00. (E, and G, on one belt Z, to alternate, $10.00.)

Anteversion, Solid StemC, or Solid Stem Globe Top G, on X, or Y, Cotton, $5.50. On Y, Satin, $6 00; Coutil, $6.50, and on Z, $4.50 only.

Rules.—The Stem Supporters Fig. 1 and 5, are only sold complete and on any of the belts selected. The Speculums, Fig. 6, only with the conductors. Globe B, or Cup D, either separate, or in connection with Stem Supporters.

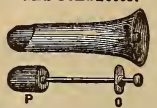
Elastic Gums S S, are mailed, 2 at 20 cts.; 4 at 35 cts.; and Springs at 3 cts. each.

Abdominal Supporter.

3.

Price—Coutil, $3.00.
" Satin, 2.50.
" Cotton, 2.00.

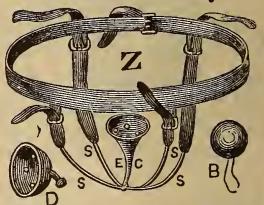
Hard Rubber Speculums and Conductor.



Sizes—1, 1 3.16, 1 6.16 and 1 9.16. Flesh color enameled. Price, $2 50 each.

SOLID STEM SUPPORTER.

E. C.—5.—(Economy.)



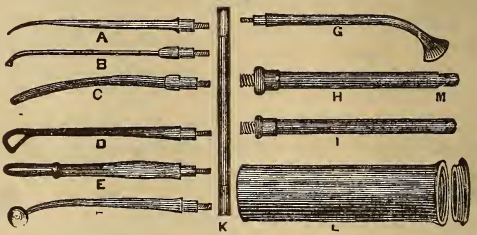
$1.50 $1.50

Price.—Curved Stem and Cup E C, (no shifting top) on elastic webbing Z, $4.50. On X, or Y, cotton, $5.50, and Y, satin, $6.00; coutil, $6.50.

No expense has been saved to give even this Economical Supporter all possible advantages.

HARD RUBBER UTERINE EXAMINING CASE.

12.



Prices.—Full case, $8.00; Quill Caustic Holder H, or Camel's Hair Brush Holder and Case I, each $1.00. Any two of the first seven, with centre piece K, $2.50.

N. B.—The figures on these engravings correspond with those on the full Catalogue plate.

Selection.—The success of a Uterine Corrector and Supporter depends on the size and style. If a cup, it must be modeled after the junction of the axis of the uterus and vagina, or the cervix will ride on the anterior edge of the cup. I U, Fig. 1, is a fair representation of this adaptation and border cup. In cases of slight Anteversion or slight Retroversion, deep cups may be called for, and in most cases the mere elevation with them corrects the trouble. The cups are usually selected by giving the full diameter across the top, thus for Virgins, $1\frac{1}{4}$ to $1\frac{5}{8}$; Multiparae, $1\frac{5}{8}$ to 2, and Procidentia, $2\frac{1}{2}$ inches and over sometimes. *Belts*—For X and Z, waist measure to be given, and Y, hip measure.

Anteversion C, Fig. 1.—This had been remodeled a number of times, and the fenestrated top found best to remain in position.

Retroversion E.—This has likewise passed through many changes, until it arrived at its present efficiency. The broad lever lifts up the fundus, while the cup corrects the prolapsus and holds the uterus, by a double elastic motion, if a spring stem. Small, long stem Globe Tops G, Fig. 1, are placed with success against the sensitive fundus, after everything else been intolerable; also a small Globe top G, on a short stem, takes the lead as an anteversion supporter.

Intra Uterine Stem Cup I U.—The stem locks in a square socket after the cup is in position. This is safer than all other contrivances. but is seldom required, since such ample provision is made in this series to correct Retroversion through the posterior cul-de-sac.

Cystocele and Rectocele.—These are successfully drawn up by large, hollow and light Globe Tops G, or oblong H, Fig. 1.

Cup D, Fig. 5.—Supplements E C, similar to Shifting Top A, when transformed into A D, Fig. 1, by screwing on F.

Globe B, Fig. 5:—This is a mere hard rubber shell, with all the objectionable features of the former glass globes overcome, and is now again a popular pessary.

Speculum, Fig. 6.—The conductor, with hollow bulb P, is shown seperate and in position. By the conductor a larger size may be introduced; this, together with the thin shell, gives a sufficient calibre to embrace the entire cervix within the mouth of the speculum. The polished edge facilitates the enclosure of the cervix by rotation.

Examining Case, Fig. 12.—Sounds A, B, C, Movers D, F, and G, with Swab E, will screw on K, and on M, of H, and form instruments 12 inches long. L, encases the 10 pieces—Wt. 4 oz.

Belt Y, Fig. 3.—Is made to order of any size and strength, to support the stem supporter and pendulous abdomen. Hip Straps S S, are elastic.

TANRET'S PELLETIERINE.

For the TREATMENT of TAPE-WORM (Tænia Solium).

This new Tanifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive uss in France, for the treatment of Tape-worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charite, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Prof. Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and if certain preliminaries are observed success will be insured.

PELLETIERINE is prepared by Mr. CHAS. TANRET, Pharmacien de First Class, 64 Rue Basse du Rempart, Paris. 1242eow-t

GENERAL AGENTS, E. FOUGERA & CO., 30 N. William St., N. Y.

VINUM DIGESTIVUM (PROCTER.)

DIGESTIVE WINE, used with unvarying success by so many of our prominent physicians for the last three years, is offered with increased confidence to the profession as a sure and rapid means for the exhibition of the artificial digestive function. The nausea of pregnancy and sea sickness are greatly alleviated or entirely relieved by its use. One fluid-ounce dissolves 500 grains of coagulated albumen. One or two teaspoonfuls may be given, or varied as desired. We would suggest that the above title be used in prescribing. 1257-1308, 1y.

Manufactured by **WM. PROCTER, Jr., CO.**, S. W. Cor. 9th and Lombard Sts., Phila.

In corresponding with Advertisers please mention THE MEDICAL AND SURGICAL REPORTER.

MURDOCK LIQUID FOOD CO., Boston,

THE ONLY MANUFACTURERS OF

RAW FOOD EXTRACTS IN THE WORLD.

It can be retained by the weakest stomach, when all other food extracts, and even water, is rejected.

Nutritious food, if raw, condensed, and free from insoluble matter, will cure chronic diseases, as it will make blood faster than all preparations or food, and new blood will cleanse the system.

MURDOCK'S LIQUID FOOD is made from Beef, Mutton and Fruits; contains corpuscles; is 12½ per cent. soluble albumen, and free from insoluble matter, drugs, minerals, salts and acids, and can be retained by the stomach when so weak as to refuse food.

Ask your Druggists, or send to us, for Essays read before the American Medical Association, at Richmond, Va., May 6, 1881, on the value of Raw Food Extracts, by Geo. R. Shepherd, of Hartford, Conn., and other Essays and Testimonials from Medical Journals and Physicians that have used Liquid Food, in cass of Consumption, Scrofula, Nervous and General Debility, Dyspepsia, acute and chronic, Constipation, Diphtheria, Intemperance, Cholera Infantum, Infantile Diarrhœa, Post-partum Hemorrhage, Purpura Hemorrhagica with Waxy Liver, Pelvic Cellulitis, Malarial and other Fevers, Chronic Strumous Arthritis, Sclerosis of the Spinal Cord, Senile Gangrene, Perinephritic Abscess, and other diseases of malnutrition. No cases of Cholera Infantum have occurred where it has been used daily, and no lives have been lost from Cholera Infantum where it has been prescribed by a physician. Excellent for Eczema, Diabetes, Rheumatism and Neuralgia.

At the request of any physician who has not tried our Extracts, and would like to, we will deliver sample bottles to the Express in Boston. To any Medical Society wishing to investigate the value of our Extracts, through a committee, hospital, or individual members, we will furnish a supply of Liquid Food equal to a six-ounce bottle for every member present at the time of action. We are induced to do this, knowing that our Extracts are saving life, and that an increased use of them, which will follow after a trial of them, will be the means of saving more lives daily. (*We ask no testimonials of results obtained.*) Raw Extracts are available where cooked ones are not, or if available, contain only one-third as much nourishment.

Liquid Food is in general use at all Hospitals, Infant and Insane Asylums, and Washingtonian Homes, U. S. Navy Hospitals, and by all physicians that have tried it.

If not kept by your Druggist, can be obtained in any of the commercial cities. In Philadelphia, by Johnston, Holloway & Co., Boericke & Tafel; in Pittsburg, by A. Kelly & Co.; in Baltimore, by Thomsen & Wirth; or you can order direct and we will pay express. 1 oz., 15 cents; 6 oz., 55 cents; 12 oz., $1.00.

See Philadelphia MEDICAL AND SURGICAL REPORTER, *Boston Medical and Surgical Journal*, and *New York Medical Record*, for chronic cases that were at our quarterly reception to physicians, in Boston, December 30, 1881—cases of Eczema, Rheumatism, Neuralgia, Diabetes, Consumption, and other diseases. If all were not restored to perfect health, they were gaining daily, and able to enjoy life and attend to their business. 1297-1348

MURDOCK LIQUID FOOD CO., BOSTON.

It is the only food that will relieve the Consumptive from Hunger.

It will make Blood faster than all preparations known.

DR. McINTOSH'S ELECTRIC OR GALVANIC BELT.

This Belt is a perfect Galvanic Battery, composed of sixteen cells, placed in pockets on a belt. Each cell is made of hard vulcanized rubber, lined with copper, which constitutes the negative plate. The rubber coating perfectly insulates each cell. The positive plates are of zinc, wrapped in a porous material to absorb the exciting fluid, preventing contact with the copper, and permitting the current to pass from the copper to the zinc. The cells are charged without wetting the belt.

A current selector is so arranged that one or more cells can be used at pleasure. The electrodes are covered similar to ordinary battery electrodes, and connected with the cells by connecting cords. By this arrangement, a current from the belt can be applied to any part of the body. Physicians who have used this belt in their practice do not hesitate to recommend it to the profession.

Our pamphlet on "Medical Electricity," containing a full description of the belt and diseases, with manner of treatment, sent free on application. Address

Registered COSMOLINE Trade Mark.

Unguentum Petrolei

Prepared by E.F.Houghton & Co. Philadelphia, U.S.A.

Put up in 1, 5, 10, 25, 50, and 100-lb. cans. Samples furnished on application. The post-office laws forbid anything of an oleaginous nature being sent through the mail.

In chemical composition, Cosmoline [Unguentum Petrolei] is an oleaginous hydrocarbon, corresponding to the heavy petroleum oils, and containing a large amount of the paraffines and olefines of the formulæ $C_{16}H_{34}$ and $C_{16}H_{32}$. It contains but a small percentage of the paraffines and olefines, corresponding to the formulæ C_7H_{16} and C_7H_{14}, respectively, and the offensive and irritating properties of the crude oil have been carefully removed. In the process of purification, no acids, alkalies, or other chemicals are employed, and no injurious additions of any kind are made to the natural product. The result is a semi-solid, translucent substance, with a faint odor and unctuous feel.

Cosmoline [Unguentum Petrolei] melts at about 100° Fah. (38° Cent.); and boils at about 625° Fah. (329° Cent.); its specific gravity is about 0.875 at 60° Fah.

As it contains no oxydizable or organic matter capable of change by putrefaction or fermentation, and is absolutely without affinity for moisture, it offers to the profession an admirable unguent, which can never decompose, ferment, or become rancid in any climate or temperature.

291 MADISON AVENUE, NEW YORK, February 26th 1878.

I have examined the preparations of Cosmoline as manufactured by E. F. Houghton & Co., Philadelphia, and believe them well adapted to the purposes for which they are designed. As lubricants, and as the bases of simple or medicated ointments, they have a decided advantage over the fixed oils and fatty substances in ordinary use, in that they do not become rancid, and do not acquire irritating qualities from atmospheric exposure. ALFRED C. POST, M.D., LL.D.,
Emeritus Professor of Clinical Surgery in the University of New York, Visiting Surgeon to Presbyterian Hospital, etc.

PHILADELPHIA, July 10, 1880.

MESSRS. E. F. HOUGHTON & CO.:

I have for a number of years made extensive use of Cosmoline [Unguentum Petrolei] and consider it a most valuable article for surgical purposes. Either as a dressing by itself, or as a vehicle for the application of medicaments, it is greatly superior to lard or other fatty matters, especially by reason of its non-liability to change by time or temperature.

Yours truly,
JOHN H. PACKARD, M.D.
1031 WALNUT ST., PHILADELPHIA.

MESSRS. E. F. HOUGHTON & CO.:

I have used extensively Cosmoline [Unguentum Petrolei] both in Dispensary and private practice, with very great satisfaction. As a vehicle in making ointments it is invaluable, and far superior to lard, for the reason that it will not become rancid or undergo chemical change like the latter, when exposed to the atmosphere. I cannot too highly commend it as an application in various skin diseases.

Yours truly, JOHN V. SHOEMAKER, A.M., M.D.,
Physician to the Pennsylvania Free Dispensary for Skin Diseases

208 WEST 34TH ST., NEW YORK.

MESSRS. E. F. HOUGHTON & CO.:

Gents:—I fully appreciate the value of your Cosmoline, or Unguentum Petrolei, and prescribe it frequently in ointments. Fluid Cosmoline I have used constantly for several years, as a lubricant of urethral sounds. It is the cleanest oil I know of for this purpose.

Yours truly, GEO. HENRY FOX.

MEDICAL ENDORSEMENTS.

We append, *by permission,* a few names of the many prominent Members of the Medical Profession who are prescribing our Maltine Preparations :

J. K. BAUDUY, M. D., St. Louis, Mo.,
Physician to St. Vincent's Insane Asylum, and Prof. Nervous Diseases and Clinical Medicine, Missouri Medical College.

WM. PORTER, A. M., M. D., St. Louis, Mo.

E. S. DUNSTER, M. D., Ann Harbor, Mich.,
Prof. Obs. and Dis. Women and Children University and in Dartmouth College.

THOMAS H. ANDREWS, M.D., Philadelphia, Pa.,
Demonstrator of Anatomy, Jefferson Medical College.

B. F. HAMMEL, M. D., Philadelphia, Pa.,
Supt. Hospital of the University of Penn.

F. R. PALMER, M. D., Louisville, Ky.,
Prof. of Physiology and Personal Diagnosis, University of Louisville.

HUNTER McGUIRE, M. D., Richmond, Va.,
Prof. of Surgery, Med. Col. of Virginia.

F. A. MARDEN, M. D., Milwaukee, Wis.,
Supt. and Physician, Milwaukee County Hospital.

L. P. YANDELL, M. D., Louisville, Ky.,
Prof. of Clinical Medicine and Diseases of Children, University, Louisville.

JOHN. A. LARRABEE, M. D., Louisville, Ky.,
Professor of Materia Medica and Therapeutics, and Clinical Lecturer on Diseases of Children in the Hospital College of Medicine.

R. OGDEN DOREMUS, M.D., LL.D., New York.
Professor of Chemistry and Toxicology, Bellevue Hospital Medical College; Professor of Chemistry and Physics, College of the City of New York.

WALTER S. HAINES, M. D., Chicago, Ill.,
Professor of Chemistry and Toxicology, Rush Medical College, Chicago.

E. F. INGALLS, A. M., M. D., Chicago, Ill.,
Clinical Professor of Diseases of Chest and Throat, Woman's Medical College.

H. F. BIGGAR, M. D.,
Prof. of Surgical and Medical Diseases of Women, Homœopathic Hospital College, Cleveland, Ohio.

DR. DOBELL, London, England,
Consulting Physician to Royal Hospital for Diseases of the Chest.

DR. T. F. GRIMSDALE, Liverpool, England,
Consulting Physician, Ladies' Charity and Lying-in Hospital.

WM. ROBERTS, M.D., F.R.C.P., F.R.S., Manchester, England,
Prof. of Clinical Medicine, Owens' College School of Medicine; Physician Manchester Royal Infirmary and Lunatic Hospital.

J. C. THOROWGOOD, M.D., F.R.C.P., London, England,
Physician City of London Hospital for Chest Diseases; Physician West London Hospital.

W. C. PLAYFAIR, M. D., F.R.C.P., London, England,
Prof. of Obstetric Medicine in King's College, and Physician for the Diseases of Women and Children to King's College Hospital.

W. H. WALSHE, M.D., F.R.C.P., Brompton, England,
Consulting Physician Consumption Hospital, Brompton, and to the University College Hospital.

A. WYNN WILLIAMS, M.D., M.R.C.S., London, England,
Physician Samaritan Free Hospital for Diseases of Women and Children.

A. C. MACRAE, M.D., Calcutta, Ind.,
Dep. Insp.-Gen. Hosp. Indian Service, late Pres. Surg., Calcutta.

EDWARD SHOPPEE, M. D., L. R. C. P., M.R.C.S., London, England

LENNOX BROWN, F.R.C.S., London, England,
Senior Surgeon, Central Throat and Ear Hospital.

J. CARRICK MURRAY, M. D., Newcastle-on-Tyne, England,
Physician to the N. C. H. for Diseases of Chest.

J. A. GRANT, M D., F.R.C.S., Ottawa, Canada.

A. A. MEUNIER, M.D., Montreal, Canada,
Prof. Victoria University.

MALTINE is prescribed by the most eminent members of the Medical Profession in the United States, Great Britain, India, China and the English Colonies, and is largely used for patients at the principal Hospitals in preference to any of the Extracts of Malt.

We will furnish gratuitously a one pound bottle of any of the Maltine Preparations to Physicians who will pay the express charges. Send for our 28 page Pamphlet on Maltine for further particulars. Address,

NEW PHARMACEUTICALS

WORTHY OF THE

Attention of Physicians.

NITRO-GLYCERINE PILLS.

Nitro-glycerine is introduced on the authority of Dr. Murrell, of London, as a remedy in angina pectoris and in cases of chronic neuralgia in any part of the body. Cases of angina pectoris which had resisted all attempts at even alleviation, much less cure, have promptly yielded to nitro-glycerine, and a number of cases of actual cure are reported. This is more than can be said of any other known remedy. In neuralgia the effects of this drug have, in some instances, been scarcely less marked.

The pill form is very eligible, besides ensuring exactness of dose.

Liquor Ergotæ Purificatus.

This form of ergot is of constant strength. In its preparation only the active principles of the drug are retained, all inert and noxious ingredients being removed. As these active principles are assayed the l quor contains them in constant and definite proportions, and thus is obviated the uncertainty of strength due to variability in the quality of the sample of the drug employed. Liquor ergotæ purificatus is as constant in its strength as morphia, quinia, or any of the other alkaloids of vegetable drugs.

Sanguis Bovinus Exsiccatus.

In this preparation of blood we have a true food, the albumen being entirely retained. In this respect it differs from the various beef extracts, beef essences, etc., in the market. These preparations are, from the very methods of their manufacture, entirely deprived of albumen, the true nutritive principle of beef, and are thus not foods in any proper sense of the word.

Sanguis bovinus exsiccatus is blood deprived of nothing but its water and fibrin, which latter is naturally small in quantity and practically of no nutritive value.

CASCARA CORDIAL.

This laxative and alterative preparation stands unequaled among pharmaceutical preparations as a remedy in constipation. Its agreeable and efficient action has been abundantly attested by the medical profession of this country, and it stands now as a remedy of unquestionable efficacy in chronic constipation. Great care should be exercised in not prescribing too large a dose, inasmuch as cascara sagrada, its active ingredient overcomes constipation by its tonic action on the bowel, rather than by direct laxative influence.

NOTES ON THE USE OF PEPSINE IN MEDICINE,

WITH RECOMMENDATIONS REGARDING SACCHARATED AND PURE PEPSINE.

That many of the diseases from which mankind suffer during infant and adult life are caused by malnutrition, there can be no doubt; and the extent to which non-assimilation of the life-giving properties of food interferes with recovery from severe illness, baffling the best directed efforts of the physician, points the necessity for an agent sufficiently potent to replace the deficient principle and aid nature in renewing the degenerated tissues.

Realizing this need, the science of chemistry produced pepsine; and even if medical literature were silent as to testimony of the results obtained, the large amount manufactured and consumed would amply attest its usefulness. But such is not the case, for, after long and careful investigation on the part of practical therapeutists, it is accepted as the remedy *par excellence* in all cases where the gastric juice fails to afford a sufficient amount of ferment for the reduction of aliment to a condition suitable for healthy assimilation.

As the undoubted value of pepsine as a remedial agent became evident, competition in its manufacture was stimulated; and as a natural result, the supply was varied both in purity and strength, and the medical profession, while anxious to avail themselves of its usefulness, were nearly as often misled into erroneous conclusions regarding its efficacy, as satisfied with its results, solely in consequence of their misfortune in not using such qualities as were likely to produce the much-lauded effects. Under these circumstances, a definite understanding regarding reliable preparations is desirable, and of great importance. Pure pepsine, without acid, thoroughly triturated with finely powdered sugar of milk (saccharated pepsine*), will, without doubt, produce the perfect results in all cases where the remedy is exhibited.

Routh, in his "Infant Feeding," gives an account of a result obtained in the case of an infant. "Small, wrinkled, emaciated, four days old, yet presenting almost the appearance of decrepitude. The voice was weak but distinct, and respiration not obstructed. The mother was an excellent nurse, but, although the infant took the breast readily, it constantly threw up every meal. What passed through the bowels was unchanged, although slightly tinged with bile. Diarrhœa was also present." The usual external remedies were applied, but without avail. "Emaciation was on the increase; the child was, in fact, dying." At this stage saccharated pepsine was administered, fifteen grains divided into ten powders, mixed with a little of the mother's milk, and after the second day the diarrhœa ceased and the child appeared much stronger. Twenty days of this treatment and the child was quite well. The eminent author adds: "This is a case which speaks strongly to the convictions. If at so early a period of life, when vitality and digestion were so weak, the artificial pepsine effected a cure, *a fortiori* will it be likely to do so in the case of older children; and so I have found it in practice. The digestive powers are thus assisted, and the food, which before was useless because undigested, readily becomes assimilated."

When administering pepsine, the slight acidity of the natural fluid should be produced as nearly as possible, and, as the necessities differ with the circumstances, it is desirable that the preparation be quite free from acidulation, and the proper dose be given in combination with the requisite amount of dilute acid. Of Kidder & Laird's pure pepsine, five to ten grains for an adult can, if necessary, be taken in an ounce of water, with five drops of muriatic acid.

For infants, however, the saccharated pepsine will be found to yield the most satisfactory results, and the acid should be dispensed with. Quantitatively it represents one-tenth of the strength of pure pepsine; but it has been found to be but about one-fourth less in efficacy. The absence of acid, which would otherwise tend to produce harmful results, will be recognized when it is considered that even the slight acidity of most cow's milk, when used as food for infants, is sufficient to disagree with them.

With regard to the proper time for its administration, as before or after taking of food, opinions vary, but reason would suggest that about half an hour before eating will afford the ferment a sufficient time to combine with the existing condition of the stomach, and produce the most natural effect upon the food when it has been acted upon by the salivary fluids in its passage to the stomach.

When once the formation of peptone has been established in the stomach, and as strength is acquired, the system will soon respond toward resuming the natural production of its normal fluids. Thus it is that many of the disorders of digestion which accompany severe attacks of fever, phthisis, etc., and also the exceedingly sensitive condition of the stomach caused by vomiting in pregnancy and alcoholism, are controlled, and a natural condition resumed.

Having mentioned the necessity of great care in the selection of pepsine, with reference to its purity and strength, it is proper to say that, even with the superior article above recommended, negative results may be obtained, unless attention is given to the form of its administration. Combinations beyond those above mentioned are not advised, but rather discouraged, as many of the substances usually recommended as efficacious with it are incompatible and render the pepsine inert.

* Saccharated pepsine, free from acid, is prepared by Messrs. Kidder & Laird, No 83 John Street, New York, who generously furnish samples of both this and the pure pepsine, free of charge, upon application.

1264-1315

IN MORNING SICKNESS

AND OTHER DISEASES

INCIDENT TO PREGNANCY.

The action of the Acid Phosphate upon the system during pregnancy is very effective; the morning sickness being treated with good results; and where indigestion is a sympathetic trouble it has been found a valuable and pleasant remedy.

In cases of exhaustion and nervous prostration from lactation, it has been used with excellent results.

During pregnancy the consumption of phosphate of lime is very great; so that at this period of woman's life fractures heal, if at all, with great difficulty. The Acid Phosphate supplies the phosphates needed at such times.

DR. D. T. NELSON, of Chicago, says: "I find Horsford's Acid Phosphate a pleasant and valuable remedy in indigestion, particularly in pregnant women."

DR. W. L. ATLEE, of Philadelphia, says: "Having used Horsford's Acid Phosphate very extensively in my practice, which consists mostly of uterine diseases and disorders incident thereto, it is with pleasure I attest my appreciation of its usefulness."

Let the patient put eight or ten drops of Acid Phosphate into half a glass of cold water, and take a sip of it, say a few minutes before rising, or whenever the sickness or nausea is coming on.

It is equally effective in hot water, or tea without milk or sugar, and to some may thus be more palatable. In such cases use the same dilution as above. Some constitutions may need a stronger dilution, which fact experience alone can decide.

Prices reasonable. Pamphlet giving further particulars mailed free on application to manufacturers.

Physicians desiring to test it will be furnished a bottle free of expense, except express charges.

MANUFACTURED BY THE

RUMFORD CHEMICAL WORKS

1297-1348 PROVIDENCE, R. I.

An experience of more than a quarter of a century convinces us that sugar, properly applied, is the only correct coating for a pill.

Physicians should be careful to specify Warner & Co., when prescribing or ordering.

Special attention is called to the following selected Recipes prepared for Physicians' Prescriptions.

PIL: PHOSPHORI COMP: (WARNER & CO.)

℞. Phosphori, - - 1-100 gr.
Ext. Nuc. Vom. - ¼ gr.

THERAPEUTICS.—As a nerve tonic and stimulant, this form of pill is well adapted for such nervous disorders as are associated with impaired nutrition and spinal debility, increasing the appetite and stimulating digestion.

The practical value of Phosphorus as a therapeutic agent, and its applicability to the cure of disease, and especially in those varied disordered conditions consequent upon OVERWORK, which are characteristic of modern civilization.

Pil. Phosphori Comp. may be taken, one or two pills three times daily, after eating.

Price, per 100, $1.50.

PIL: IODOFORM ET FERRI. (WARNER & CO.)

℞. Iodoform, - - 1 gr.
Ferri Redacti, - 1¼ gr.

THERAPEUTICS.—A powerful general tonic and alterative, valuable as a remedy in Anæmia, Scrofula, Neuralgia, Chlorosis, Rheumatism, etc.

Pil. Iodoform et Ferri may be given in doses of from one to two pills, as occasion may require.

Price, per 100, $2.00.

PIL: DIGESTIVA. (WARNER & CO.)

℞. Pepsin Conc't, 1 gr. Gingerine, 1-16 gr.
Pv. Nuc. Vom., ¼ gr. Sulphur, ⅛ gr.

THERAPEUTICS.—Useful in relieving various forms of Dyspepsia and Indigestion, and of permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. It is also a gentle laxative and excellent dinner pill, may be taken one after dinner, or one before each meal, three times daily.

Price, per 100, 75 cts.

PIL: CALCIUM SULPHIDE. (WARNER & CO.) 1-10, ¼, ½ & 1 gr. each.

THERAPEUTICS.—Extremely useful in the treatment of acne, scrofula and cutaneous diseases.

Sulphide of Calcium is usually administered in doses of from 1-10 to ¼ grain four times daily, gradually increasing the dose to one grain six times daily, or according to the progress or severity of the case.

Price, per 100, 1-10 gr. .50; 1-4 gr. .60; 1-2 gr. .75; 1 gr. $1.00.

WARNER & CO.'S PILLS MAY BE OBTAINED FROM ALL DRUGGISTS, OR BY MAIL, ON RECEIPT OF PRICE.

SOLE AGENTS FOR THE UNITED STATES,

41 & 43 WARREN STREET, NEW YORK.

1273-1325eow

SAVORY & MOORE beg to call the attention of the Profession to some of their Special Preparations, the purity and uniform strength of which are Guaranteed.

PANCREATIC EMULSION,

Prepared in accordance with the direction of the Physician who introduced this purely

MEDICINAL FOOD FOR CONSUMPTION AND WASTING DISEASES.

Pancreatic Emulsion will always take precedence of Cod-Liver Oil, by reason of its introducing the STABLE SOLID FATS INTO THE SYSTEM, instead of the evanescent fluid fats or oils.

Neither Cod-Liver Oil nor EMULSIONS of COD-LIVER OIL can supply the kind of fat necessary for sound and vigorous human life. In addition to this, all the Oily Emulsions are liable to rancidity, and most of them are highly objectionable in consequence of the SAPONIFICATION and ULTIMATE PUTREFACTION, produced by the chemical agents used instead of Pancreatic Juice.

Pancreatic Emulsion (properly so-called), is THE NECESSARY FOOD OF THE CONSUMPTIVE, and the most reliable form of nutriment for counteracting the tendency to Phthisis and other wasting diseases. It presents to the lacteals fat, in essentially the same condition for assimilation and absorption as in a vigorous human frame, and THE AGENT of the important change is THE NATURAL SECRETION of the PANCREAS.

Pancreatic Emulsion may therefore be regarded as Chyle obtained by nature's own process. In certain cases both Cod-Liver Oil and Pancreatic Emulsion are required—one to supply the blood with oil or liquid fat, the other with the more stable solid fats; but it cannot be too strongly urged that both PANCREATIC EMULSION and Cod-Liver Oil are *not to be regarded as Medicines, but as articles of diet*, without which patients, with their defect of health, will as surely starve as healthy persons would if deprived of the most nutritive part of their food.

Pancreatized (Digestive) Cod-Liver Oil. By Pancreatized Cod-Liver Oil, the active digestive principle of the Pancreatic Juice is imparted to it, which renders it in a highly favorable condition for rapid and complete digestion and assimilation, preventing nausea, and largely increasing the beneficial properties of the Oil.

Pancreatine effects the digestion and assimilation of Cod-Liver Oil and Fat, as well as Food generally. This palatable and popular remedy is therefore invaluable to PATIENTS WHO ARE UNABLE TO DIGEST COD-LIVER OIL, and who are thus deprived of its nourishing and invigorating properties.

Pancreatine Wine. An excellent vehicle for taking Cod-Liver Oil and promoting the digestion of it.

Tins, 1*s*, 2*s*, 5*s*, 10*s*.

AS SUPPLIED TO

THE ROYAL NURSERIES

Of England, Russia, Etc.,

AND CONTAINING THE

HIGHEST AMOUNT OF NOURISHMENT

IN THE

MOST DIGESTIBLE AND CONVENIENT FORM.

THE MOST PERFECT SUBSTITUTE FOR HEALTHY MOTHER'S MILK.

1244-1295 **Agents for America, E. FOUGERA & CO., NEW YORK.**

VACCINE VIRUS,

AND

PRICES REDUCED. VACCINATORS PRICES REDUCED.

We continue, as for several years, to supply **ANIMAL VIRUS** propagated at our own stables from lymph of the "Beaugency Stock," imported by ourselves expressly for this purpose. Results of experience enable us to recommend it as of unsurpassed excellence.

The establishment is under the care of a competent physician of long experience in this specialty, who will spare no pains to produce a perfectly *reliable* and *pure* article, which we are prepared at all times to furnish in *fresh* and *active* condition.

Our new method Kine Crusts will be found much superior to the ordinary form, though points are recommended as the most reliable form of virus attainable.

All our Virus is put up in strong, *air-tight*, *sealed packages*, for safe conveyance by mail or express, and will be sent (postpaid if by mail) upon the following terms:—

Fifteen large Ivory Points, well charged on both sides.....$2.00
Seven large Ivory Points, well charged on both sides. 1.00
Large Ivory Points, less than seven, well charged on both sides, each..... .25
One Crust, new method, in air-tight Glass Capsule, prepared for immediate use..... 2.00

Also **Humanized Virus,** from HEALTHY CHILDREN, procured for us by physicians of undoubted reliability.

One Crust from Unruptured Vesicles (one remove from heifer if preferred).....$2.00

We will give a fresh supply, in case of failure reported within twenty days for Points, thirty days for Human, and ninety days for Kine Crusts.

Orders by mail or telegraph answered by return train.

Liberal discounts upon large supplies for Cities, Towns and Institutions.

Scarifying Vaccinator. Steel, Nickel Plated. (See Cut.) Each 25 cents.

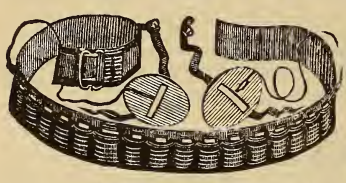
ALL WITH TAPES. 1246-1297eow

DR. McINTOSH'S ELECTRIC OR GALVANIC BELT.



This Belt is a perfect Galvanic Battery, composed of sixteen cells, placed in pockets on a belt. Each cell is made of hard vulcanized rubber, lined with copper, which constitutes the negative plate. The rubber coating perfectly insulates each cell. The positive plates are of zinc, wrapped in a porous material to absorb the exciting fluid, preventing contact with the copper, and permitting the current to pass from the copper to the zinc. The cells are charged without wetting the belt.

A current selector is so arranged that one or more cells can be used at pleasure. The electrodes are covered similar to ordinary battery electrodes, and connected with the cells by connecting cords. By this arrangement, a current from the belt can be applied to any part of the body. Physicians who have used this belt in their practice do not hesitate to recommend it to the profession.

Our pamphlet on "Medical Electricity," containing a full description of the belt and diseases, with manner of treatment, sent free on application. Address

McINTOSH GALVANIC BATTERY CO.,

1281-1332 **192 AND 194 JACKSON STREET, CHICAGO, ILL.**

COMPOUND PETROLEUM PILLS.

The attention of the *Profession* is called to my new *Combination* for the alleviation of **BRONCHIAL** and **PULMONARY TROUBLES—CONSUMPTION, CHRONIC BRONCHITIS, CATARRH** and **ASTHMA.** Sample Boxes with Formula furnished *Physicians.*

Price Fifty Cents and One Dollar per Box. Sent on receipt of price by Registered Letter.

1296-1347 **JAMES STOKES, M.D., Irving, Chautauqua County, N. Y.**

PROCTER'S PEPSIN (SACCHARATED.

This standard article is prepared from *Pepsin*, carefully purified and freed from mucus, and is not a *dried Peptone.* It is inodorous and non deliquescent, and retains its digestive power indefinitely. It is so well known that extended comment is superfluous. We would, however, call attention to its uniform purity and solubility, which, with extraordinary *digestive power*, commend its use in preference to other less carefully *made* articles. It is tested to the solution of 250 grains of coagulated albumen by 10 grains of Pepsin.

PROCTER'S "PEPSIN FORTIOR," (Stronger or Concentrated Pepsin.) A powerful form of Pepsin, eligible when minimum dose is desirable. It is of the same exceptional purity with our *Procter's Pepsin*, while the strength is far greater. Dose one to three grains. 1275-1308, 1y.

Manufactured by WM. PROCTER, Jr., CO., S. W. Cor. 9th and Lombard Sts., Phila.

Just Out! New and Valuable Publications!

The Physician's Clinical Record and Case Book.

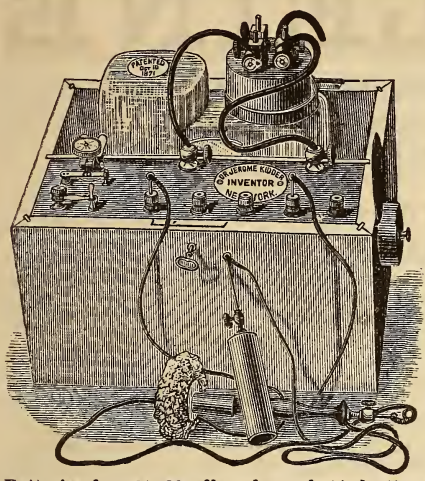
FOR 100 PATIENTS.

Neatly Bound in Cloth, with Pocket and Stencil Plate, Price $1.00.

This very convenient little book, adapted to be carried in the pocket, gives, in the briefest and neatest arrangement, the best forms of preserving the records of cases. A brass Stencil Plate accompanies each book, for rapidly sketching an outline of the body, in which may be marked, by shading, the seat of effusions, etc., or the size and position of organs, tumors, etc.

Several pages of Prefatory matter are given, presenting in the most succinct form a number of memoranda to refresh the memory of the practitioner, as: 1. Memoranda in Examining Patients; 2. Symptoms of Poisoning, etc.; 3. The Urine in Disease. Ruled Temperature Charts are added.

DR. JEROME KIDDER'S
ELECTRO-MEDICAL APPARATUS.



For which he has received Letters Patent for improvements rendering them superior to all others, acknowledged by awards of First Premium at Centennial, also First Premium by American Institute from 1872 to 1880 inclusive, and in 1875, Gold Medal.

☞ Please note the following for which the

GOLD MEDAL

Was awarded by American Institute in 1875, to distinguish the Apparatus as of the **First Order of Importance.**

Dr. Jerome Kidder's Improved No. 1. Physician's Office Electro-Medical Apparatus.

Dr. Jerome Kidder's Improved No. 2. Physician's Visiting Machine, with turn-down helix.

Dr. Jerome Kidder's Improved No. 3. Physician's Visiting Machine (another form).

Dr. Jerome Kidder's Improved No. 4. Office and Family Machine.

Dr. Jerome Kidder's Improved No. 5. Tip Battery, Ten Current Machine (See cut), a most perfect and convenient apparatus, the invention of Dr. Kidder.

We also make and keep on hand superior Galvanic Cell Batteries, from 6 to 36 cells; also pocket induction apparatus. For Illustrated Catalogue address

OSMUN'S
PREPARED COD LIVER OIL
—AND—
LACTO-PHOSPHATE of LIME.

Sold by Druggists.

From *Physician and Pharmacist:*—"C. A. OSMUN has received from many members of the profession emphatic endorsement of his preparation of Cod-liver Oil and Lime. The growing demand for the article during the past year is one of the best evidences that the results obtained in its use have been thoroughly satisfactory. The oil used is Norwegian, and the lime is carefully prepared in his own laboratory, thus ensuring from his personal superintendence a reliable remedy in every particular.
